1.0 Background

Liquid that exits from a septic tank ("effluent") contains suspended solids that can cause traditional systems to fail prematurely. Solids can overload bacteria, cut off air required for aerobic bacterial activity, and/or seal the underlying soil, interfering with its ability to absorb liquid.

1.1 What Our System Does

By utilizing simple yet effective natural processes, the Advanced Enviro-Septic® Treatment System treats septic tank effluent in a manner that prevents suspended solids from sealing the underlying soil, increases system aeration, and provides a greater bacterial treatment area ("biomat") than traditional systems.

1.2 Why Our System Excels

The Advanced Enviro-Septic® Treatment System retains solids in its pipe and provides multiple bacterial surfaces to treat effluent prior to its contact with the soil. The continual cycling of effluent (the rising and falling of liquid inside the pipe) enhances bacterial growth. This all combines to create a unique eco-system that no other passive wastewater treatment system is designed to offer. The result is a system that excels by being more efficient, lasting longer, and has a minimal environmental impact.

1.3 System Advantages

- a) costs less than traditional systems
- b) eliminates the need for washed stone
- c) often requires a smaller area
- d) installs more easily and quickly than traditional systems
- e) adapts easily to residential and commercial sites of virtually any size
- f) adapts well to difficult sites
- g) develops a protected receiving surface preventing sealing of the underlying soil
- h) blends "septic mounds" into sloping terrain
- i) increases system performance and longevity
- j) tests environmentally safer than traditional systems
- k) recharges groundwater more safely than traditional systems
- l) made from recycled plastic

1.4 Patented Technology

At the heart of Advanced Enviro-Septic® system is a patented corrugated, perforated plastic pipe with interior skimmer tabs and ridges. All Advanced Enviro-Septic® pipe is surrounded by three filtering, treatment and dispersal layers. Advanced Enviro-Septic® systems are completely passive, requiring no electricity, motors, alarms, computers, etc. Advanced Enviro-Septic® pipes are assembled and installed either below or above ground in a bed of specified System Sand.

1.5 Advanced Enviro-Septic® (AES)

The Advanced Enviro-Septic® pipe is assembled into an onsite wastewater treatment system that has been successfully tested and certified to NSF 40, Class I (a certification typically given to mechanical aeration devices), BNQ of Quebec (Class I, II, III) and Cebedeau, Belgium standards. AES is comprised of corrugated, perforated plastic pipe, Bio-Accelerator® fabric along its bottom, surrounded by a layer of randomized plastic fibers and a sewn geo-textile fabric. AES creates an eco-system designed to simultaneously purify and disperse effluent after primary treatment by a septic tank. The AES system is the "next generation" of our Enviro-Septic® technology. The AES product incorporates Bio-Accelerator, a proprietary enhancement that screens additional solids from effluent, accelerates treatment processes, assures even distribution and provides additional surface area. Each ft. of AES pipe provides over 40 sq. ft. of total surface area for bacterial activity.

1.6 Effluent Filter Not Required

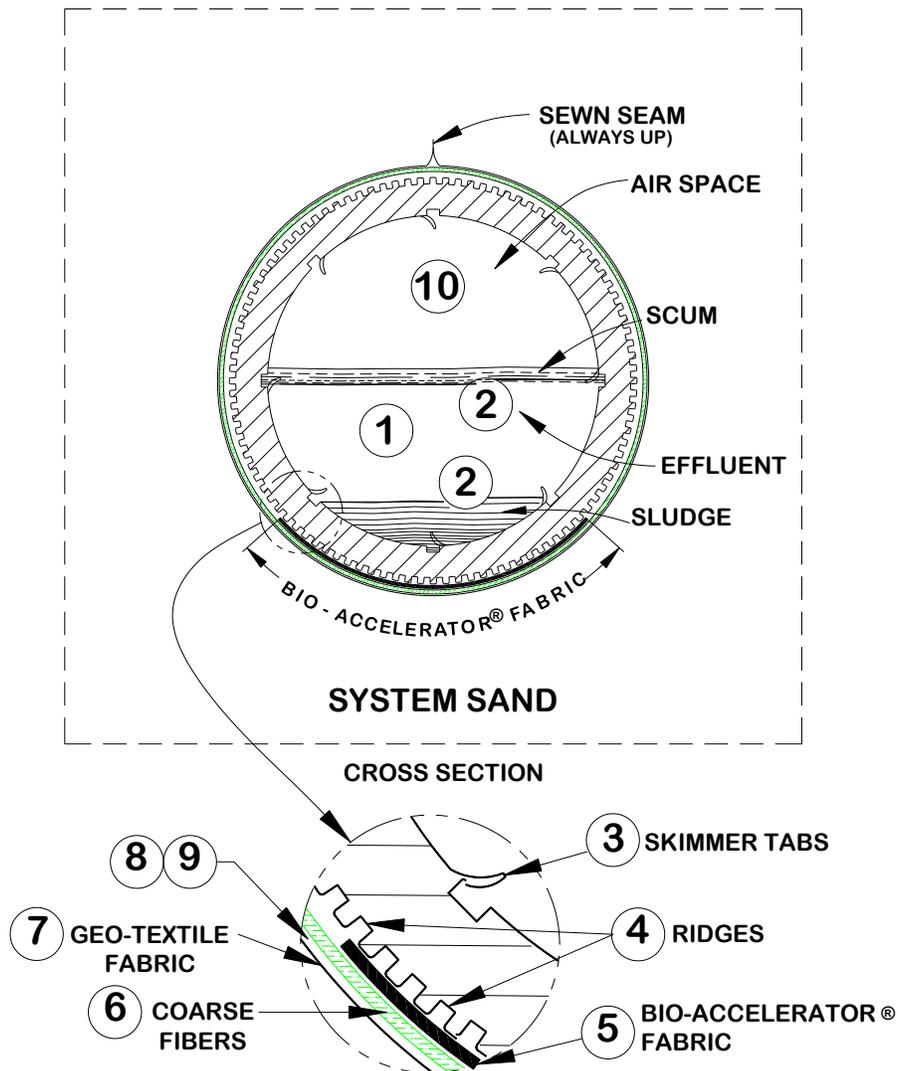

AES pipe complies with SPS 383.44 without the use of an effluent filter. AES does not disperse any solids exceeding 1/8 of an inch in diameter onto the infiltrative surface due to the design of the product and the natural process of the digestion of solids taking place within the aerobic environment in the patented AES system. AES pipe has been successfully tested and certified without the use of effluent filters. AES pipe is designed to create an eco-system designed to simultaneously purify and disperse effluent after primary treatment by a septic tank in a manner that prevents suspended solids from sealing the underlying soil. AES retains solids in the pipe and provides multiple bacterial surfaces to treat effluent prior to its contact with the soil. The continual cycling of effluent combined with passive air flow throughout the AES system enhances bacterial growth within the multiple fiber and fabric layers that make up the AES pipe. Effluent filters are not recommended for use with the AES system, but they are allowed if properly maintained.

1.7 AES System Specific Terminology

A glossary has been provided at the end of this document which contains terminology specific to the AES system. It is recommended that readers familiarize themselves with the terminology contained in this Glossary to aid in understanding terminology contained in this Manual.

2.0 Ten Stages of Wastewater Treatment

The Advanced Enviro-Septic® Wastewater Treatment System's 10 STAGES OF TREATMENT

- Stage 1:** Warm effluent enters the pipe.
- Stage 2:** Suspended solids separate from liquid effluent.
- Stage 3:** Skimmers further capture grease and suspended solids from the existing effluent.
- Stage 4:** Pipe ridges allow the effluent to flow uninterrupted around the circumference of the pipe.
- Stage 5:** Bio-Accelerator fabric screens additional solids from the effluent, enhances and accelerates treatment, facilitates quick start-up after periods of non-use, provides additional surface area for bacterial growth, promotes even distribution, and further protects outer layers and the receiving surfaces so they remain permeable.
- Stage 6:** A mat of coarse, randomly-oriented fibers separates more suspended solids from the effluent.
- Stage 7:** Effluent passes into the geo-textile fabrics and grows a protected bacterial surface.
- Stage 8:** Sand wicks liquid from the geo-textile fabrics and enables air to transfer to the bacterial surface.
- Stage 9:** The fabrics and fibers provide a large bacterial surface to break down solids.
- Stage 10:** An ample air supply and fluctuating liquid levels increase bacterial efficiency.

3.0 System Components

3.1 AES Pipe

- a) AES pipe required is calculated at 70 ft. per bedroom for residential and 2.14 GPD/ft. commercial applications. This assumes residential strength effluent.
- b) Plastic pipe made with a significant percentage of recycled material
- c) 10 ft. sections (can be cut to any length)
- d) Ridged and perforated, with skimmer tabs on interior
- e) Bio-Accelerator® along bottom of pipe (sewn seam always placed up)
- f) Surrounded by a mat of randomly-oriented plastic fibers
- g) Wrapped in a non-woven geo-textile fabric stitched in place
- h) Exterior diameter of 12 in.
- i) Each 10 ft. section has a liquid holding capacity of approx. 58 gallons
- j) A 10 ft. length of AES pipe is flexible enough to bend up to 90°

3.2 Offset Adapter

An offset adapter is a plastic fitting 12 in. in diameter with an inlet hole designed to accept a 4 in. sewer line, raised connection or vent pipe. The hole is to be installed in the 12 o'clock position. The distance from the bottom of the Offset Adapter to the bottom of its inlet hole is 7 in. When assembling pipes into rows, note that the geo-textile fabrics are placed over the edges of the Offset Adapter and Couplings.

3.3 Double Offset Adapter

A double offset adapter is a plastic fitting 12 in. in diameter with two 4 in. holes designed to accept a 4 in. inlet pipe, raised connection, vent or vent manifold, and/or bottom drain, depending upon the particular requirements of the design configuration. The 4 in. holes are to be aligned in the 12 o'clock and 6 o'clock positions as shown in the image to the right. The holes are positioned 1 in. from the outside edge of the double offset adaptor and 2 in. from each other.

3.4 Coupling

A coupling is a plastic fitting used to create a connection between two pieces of AES pipe. Note that the couplings are wide enough to cover 1 or 2 pipe corrugations on each of the two pipe ends being joined. The couplings feature a snap-lock feature that requires no tools. When assembling pipes into rows, note that the geo-textile fabric does not go under couplings. Pull fabric back, install coupling, and then pull fabric over coupling. Care should be taken during the backfilling process to ensure the fabric does not shift, providing a continuous cover of the geotextile fabric. Also, note, during installation in cold weather, couplings are easier to work with if stored in a heated location (such as a truck cab) before use.

3.5 Distribution Box

A Distribution Box, also called a "D-box," is a device used to distribute effluent coming from the septic tank in a system that contains more than one section or more than one bed. D-boxes are also sometimes used for velocity reduction. D-boxes come in various sizes and with a varying number of outlets. Concrete D-boxes are preferred; some are made of plastic. Flow equalizers (see below) are installed in the D-box openings to equalize distribution; they help ensure equal distribution in the event that the D-box settles or otherwise becomes out of level. Unused openings in D-boxes are to be covered, plugged or mortared. A distribution box is only required when dividing flow to more than one section of the bed.

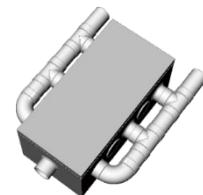

3.6 Flow Equalizers

All AES systems with Combination Serial distribution or Multiple Bed distribution must use Flow Equalizers in each distribution box outlet. A flow equalizer is an adjustable plastic insert installed in the outlet holes of a distribution box to equalize effluent distribution to each outlet whenever flow is divided. Each Bed or section of Combination Serial distribution is limited to a maximum of 15 gallons per minute, due to the flow constraints of the equalizers. Example: When pumping to a d-box going to a combination system with 3 sections (using 3 D-box outlets). The maximum delivery rate is $(3 \times 15) = 45$ GPM. Always provide a means of velocity reduction when needed.

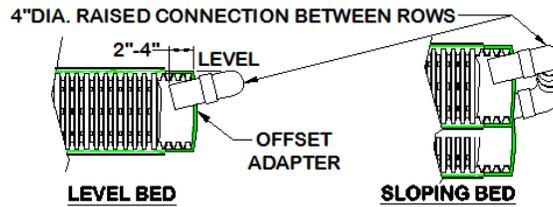

3.7 Manifolder Splitter Box

A manifolded splitter box joins several outlets of a D-box to help divide flow more accurately. Dividing flow to multiple beds is a common use of splitter boxes. All outlets delivering effluent to the field must have a flow equalizer. Do not place an equalizer on vent outlets.

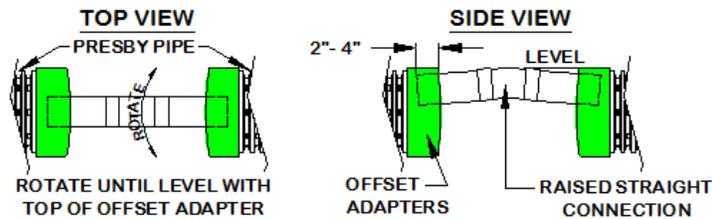

3.8 Raised Connection

A raised connection is a PVC Sewer & Drain pipe configuration which is used to connect AES rows. Raised connections extend 2 in. to 4 in. into pipe and are installed on an angle (as shown below). All PVC joints should be glued or mechanically fastened.

3.9 Raised Straight Connection

A raised straight connection is a PVC Sewer & Drain pipe configuration which is used to connect AES rows that are placed end to end along the same contour. Raised straight connections extend 2 in. to 4 in. into pipe and are installed on an angle (as shown below). All PVC joints should be glued or mechanically fastened. Offset Adapters will accept 4 in. Schedule 40 PVC if the edge to be inserted into the adapter is rounded.

3.10 Septic Tank

The AES system is designed to treat effluent that has received “primary treatment” in a standard septic tank. Septic tank capacity is determined by state and/or local rules. Septic tanks must be fitted with inlet and outlet baffles in order to retain solids in the septic tank and to prevent them from entering the AES pipes. Effluent filters are not recommended by Presby Environmental, Inc. If you are required to use an effluent filter in a gravity fed system due to State or local requirements, the effluent filter selected must be properly maintained to allow the free passage of air to ensure the proper functioning of the system.

3.11 System Sand

The System Sand that surrounds the AES pipes is an **essential** component of the system. It is **critical** that the correct type and amount of System Sand is used during construction. System Sand must be coarse to very coarse, clean, granular sand, free of organic matter. System Sand is placed a minimum of 12 in. below, 6 in. between and around the perimeter and 3 in. above the AES pipes. It must adhere to **all** of the following percentage and quality restrictions:

System Sand Specification

Sieve Size	Percent Retained on Sieve (by weight)
3/4 inch (19 mm)	0
#10 (2 mm)	0 - 35
#35 (0.50 mm)	40 - 90
Note: not more than 3% allowed to pass the #200 sieve (verified by washing sample per requirements of ASTM C-117)	

3.12 System Sand Acceptable Alternative

ASTM C-33 (concrete sand), natural or manufactured sand, with not more than 3% passing the #200 sieve (verified by washing the sample per the requirements of ASTM C-117 as noted in the ASTM C-33 specification) may be used as an acceptable alternate material for use as System Sand.

4.0 Table A: Soil Application Rate by Soil Characteristics (from Wisconsin Table SPS 383.44-2)

Soil Characteristics			Soil Application Rate (GPD/sq. ft.)	
Texture	Structure			
	Shape	Grade		
Coarse Sand, Sand, Loamy Coarse Sand, Loamy Sand	-	Structureless	1.6 ^a	0.5 ^b
Fine Sand, Loamy Fine Sand	-	Structureless	1.0

		Moderate, Strong	0.3	

a = with ≤60% rock fragments and b = with >60% to <90% rock fragments

***Applications rates less than 0.3 GPD/sf. may not have a linear loading greater than 4.5 GPD/ft.**

Note: Soil application rates shown above assume residential strength effluent (see para. 8.7, pg. 9 for definition of residential strength). Contact Presby Environmental for technical assistance with high strength wastewater.

5.0 Table B: Slope Requirements

Soil Application Rate (GPD/sq. ft.)	Maximum System Slope (%)	Maximum Site Slope (%)
1.6 – 0.6	25	33
0.5	15	20
0.3 – 0.2	5	5

6.0 Table C: Row Length and Pipe Layout Width (PLW)

		Total Linear Feet of AES Pipe													
Row Length (ft)	20	40	60	80	100	120	140	160	180	200	220	240	260	280	300
	25	50	75	100	125	150	175	200	225	250	275	300	325	350	375

*Pipe Layout Width (ft.) = Outermost edge of first row to outermost edge of last row

*Formula for Pipe Layout Width (PLW) = [Row Spacing x (# of Rows - 1)] + 1. Row spacing is 1.5 ft. minimum; larger row spacing is allowed and at the discretion of the designer. To use Table C: select a row length and move right until the minimum amount of pipe is found (more is allowed). Then move down to find the number of rows required. Continue downward in the same column until adjacent to the row spacing and find the pipe layout width.

7.0 Design Worksheet

Step #1: _____ bedrooms x 100 GPD = _____ GPD x 1.5 = _____ GPD design wastewater flow (DWF).

Step #2: _____ GPD DWF ÷ _____ GPD/sq. ft. Application Rate (Table A) = _____ sq. ft. system sand bed area (SSBA) minimum.

Step #3: Residential: _____ Bedrooms x 70 = _____ ft. of AES pipe minimum, or Commercial: _____ GPD DWF ÷ 2.14 GPD/ft. = _____ ft. of AES pipe minimum (assumes residential strength).

Step #4: _____ GPD DWF ÷ 750 GPD/section = _____ sections required. Notes: round fractions up to whole number. This step does not apply to parallel distribution systems.

Step #5: _____ ft. AES pipe (Step #3) ÷ _____ ft. row length = _____ number of rows. Notes: number of rows must be evenly divided by number of serial sections from Step #4, add rows if necessary (does not apply to parallel distribution systems). Longer rows preferred to shorter length rows.

Step #6: _____ ft. Pipe Layout Width (PLW) from Table C (or calculated manually for larger row spacing).

Step #7: _____ % system slope (cannot exceed Table B allowances).

Step #8: Calculate System Sand bed width (SSBW)–

Beds sloping 10% or less, use the larger of (a) or (b) below:

a) _____ sq. ft. sand bed area (Step #2) ÷ (_____ ft. row length + 1 ft.) = _____ ft. sand bed width minimum Note: 1 ft. is added to row length to allow 6 in. of sand beyond the ends of each row.

b) _____ ft. PLW (Step #6) + 1 ft. = _____ ft. sand bed width minimum.

Beds sloping over 10%, use the larger of (c) or (d) below:

c) _____ sq. ft. SSBA (Step #2) ÷ (_____ ft. row length + 1 ft.) = _____ ft. sand bed width minimum.

d) _____ ft. PLW (Step #5) + 4.5 ft. = _____ ft. sand bed width minimum Note: 4.5 ft. is added to the PLW to allow 6 in. of sand above the first row and 3.5 ft. beyond the edge of the lower row.

Step #9: Calculate System Sand Extension(s) choose (a) or (b) below:

Level beds (System Sand Extensions (SSE) are placed on each side of AES pipes):

a) (_____ ft. SSBW (Step #8) – _____ ft. PLW Step #5 + 1) ÷ 2 = _____ ft.

Sloping beds: SSE placed entirely on the down slope side of the bed.

b) _____ ft. SSBW (Step #8) – _____ ft. PLW (Step #5) + 1 = _____ ft.

7.1 Design Example

Single family residence, estimated daily flow three (3) bedrooms (300 GPD), Application Rate for LFS (Loamy Fine Sand), 10% sloping site, serial distribution layout.

Step #1: Three (3) bedrooms x 100 GPD x 1.5 = 450 GPD DWF

Step #2: 450 GPD DWF ÷ 1.0 GPD/sq. ft. Application Rate (Table A) = 450 sq. ft. sand bed area min.

Step #3: Residential: 3 Bedrooms x 70 = 210 ft. of AES pipe minimum.

Step #4: 450 GPD DWF ÷ 750 GPD/section = 0.6 → 1 section required.

Step #5: 210 ft. AES pipe (Step #3) ÷ 70 ft. row length = 3 rows required.

Step #6: 4.0 ft. PLW from Table C (or calculated manually for larger row spacing).

Step #7: 10% system slope (Table B allows up to 25%).

Step #8: Calculate System Sand bed width –

Beds sloping 10% or less, use the larger of (a) or (b) below:

a) 450 sq. ft. sand bed area (Step #2) ÷ (70 ft. row length + 1 ft.) = 6.34 ft. sand bed width min. (Round up to 6.5 ft.)

b) 4.0 ft. PLW (Step #6) + 1 ft. = 5.0 ft. sand bed width minimum (use 6.5 ft. from 8a above).

Step #9: Calculate System Sand Extension(s) choose (a) or (b) below:

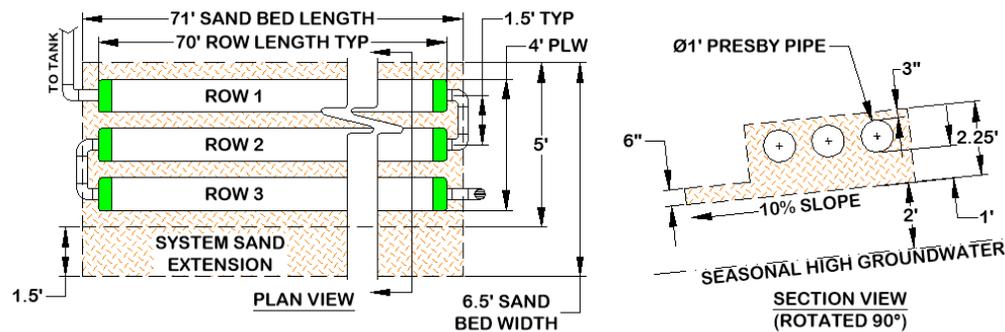

Level beds (System Sand Extensions (SSE) are placed on each side of AES pipes):

a) bed is sloping, go to 9(b)

Sloping beds: SSE placed entirely on the down slope side of the bed.

b) 6.5 ft. SSBW (Step #8) – (4.0 ft. PLW Step #6 + 1) = 1.5 ft.

Illustration of Example #1, Basic Serial Distribution:

Notes: A distribution box could have been used (parallel layout) with the distribution box being placed in-line with the highest row and then connecting to all the rows individually. Whenever possible eliminate the need for a distribution box and use a serial layout. This will ensure air passes equally through every ft. of AES pipe.

7.2 Design Example #2:

Single family residence, four (4) bedrooms (400 GPD), Application Rate for Loam (Structureless, Massive) of 0.5 GPD/sq. ft. for 60 MPI soils, level site, serial distribution layout.

Step #1: Four (4) bedrooms x 100 GPD x 1.5 = 600 GPD DWF

Step #2: 600 GPD ÷ 0.5 GPD/sq. ft. Application Rate (Table A) = 1,200 sq. ft. sand bed area min.

Step #3: Residential: 4 Bedrooms x 70 = 280 ft. of AES pipe minimum.

Step #4: 600 GPD ÷ 750 GPD/section = 0.8 → 1 section required.

Step #5: 280 ft. AES pipe (Step #3) ÷ 100 ft. row length = 2.8 rows required. Round up to 3.

Step #6: 4.0 ft. PLW from Table C (or calculated manually for larger row spacing).

Step #7: 0% system slope (Table B allows up to 15%).

Step #8: Calculate System Sand bed width –

Beds sloping 10% or less, use the larger of (a) or (b) below:

a) 1,200 sq. ft. sand bed area (Step #2) ÷ (100 ft. row length + 1 ft.) = 11.9 ft. sand bed width (use this value). Round up to 12 ft. for ease of construction.

b) 4.0 ft. PLW (Step #6) + 1 ft. = 5 ft. sand bed width minimum.

Step #9: Calculate System Sand Extension(s)

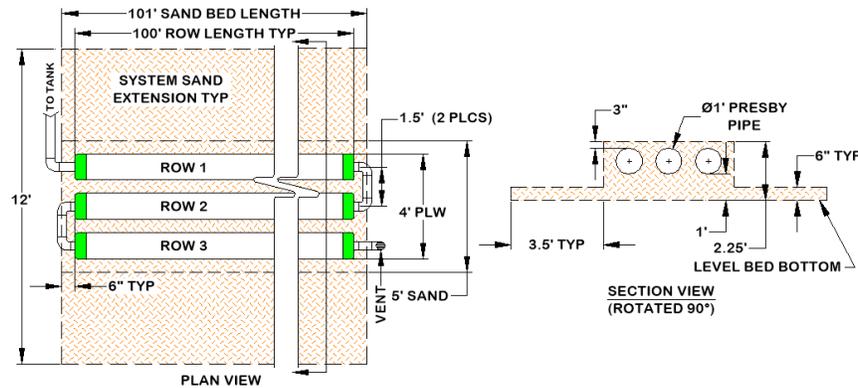

Level beds (System Sand Extensions (SSE) are placed on each side of AES pipes):

a) 12 ft. SSBW (Step #8) – (4 ft. PLW Step #6 + 1) ÷ 2 = 3.5ft.

Sloping beds: SSE placed entirely on the down slope side of the bed.

b) Level bed skip this step.

Illustration of Example #2, Basic Serial Distribution:

7.3 Design Example #3:

Commercial system, 520 GPD, Application Rate of 0.8 GPD/sq. ft. for Very Fine Sandy Loam soils, 12% sloping terrain and system, serial distribution layout.

Step #1: $520 \text{ GPD} \times 1.5 = 780 \text{ GPD DWF}$

Step #2: $780 \text{ GPD} \div 0.8 \text{ GPD/sq. ft. Application Rate (Table A)} = 975 \text{ sq. ft. sand bed area min.}$

Step #3: $780 \text{ GPD} \div 2.14 \text{ GPD/ft.} = 365 \text{ ft. of AES pipe minimum.}$

Step #4: $780 \text{ GPD} \div 750 \text{ GPD/section} = 1.1 \rightarrow 2 \text{ sections required.}$

Step #5: $365 \text{ ft. AES pipe (Step \#3)} \div 95 \text{ ft. row length} = 3.9 \text{ (round up to 4).}$

Step #6: 5.5 ft. PLW from Table C (or calculated manually for larger row spacing).

Step #7: 12% system slope (Table B allows up to 25%).

Step #8: Calculate System Sand bed width –

Beds sloping over 10%, use the larger of (a) or (b) below:

a) $975 \text{ sq. ft. sand bed area (Step \#2)} \div (95 \text{ ft. row length} + 1 \text{ ft.}) = 10.2 \text{ ft. sand bed width. Round up to 10.5 ft. (use this value).}$

b) $5.5 \text{ ft. PLW (Step \#5)} + 4.5 \text{ ft.} = 10 \text{ ft. sand bed width minimum.}$

Step #9: Calculate System Sand Extension(s)

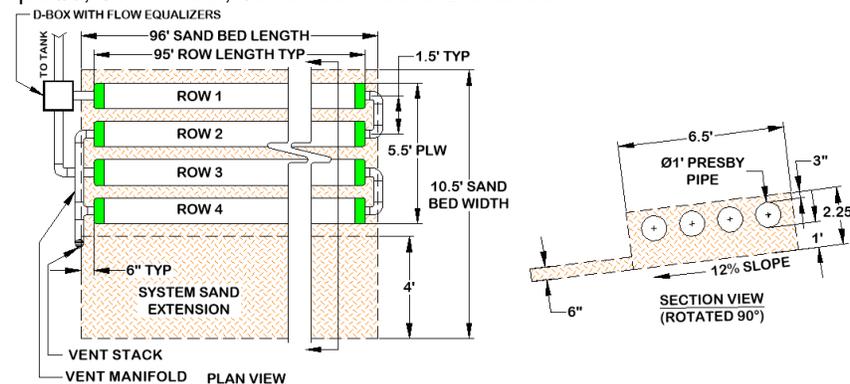

Level beds (System Sand Extensions (SSE) are placed on each side of AES pipes):

a) bed is sloping, go to 9(b)

Sloping beds: SSE placed entirely on the down slope side of the bed.

b) $10.5 \text{ ft. SSBW (Step \#8)} - (5.5 \text{ ft. PLW Step \#6} + 1 \text{ ft.}) = 4.0 \text{ ft.}$

Illustration of Example #3, Commercial, Combination Serial Distribution:

8.0 Design Criteria

8.1 AES Pipe Requirements

- a) Sewn seam must be oriented in the 12 o'clock position. This correctly orients the Bio-Accelerator fabric in the 6 o'clock position.
- b) Venting is always required regardless of vertical separation to restrictive features.

8.2 Barrier Materials over System Sand

No barrier materials (hay, straw, tarps, etc.) are to be placed between the System Sand and cover material; such materials may cut off necessary oxygen supply to the system. The only exception is the placement of the specified fabric to achieve H-20 loading requirements (see para. 17.0, pg. 17).

8.3 Certification Requirements

Any designers and installers who have not previously attended a Presby Environmental, Inc. Certification Course are required to obtain Presby Certification. Certification is obtained by attending a Certification Course presented by Presby Environmental, Inc. or its sanctioned representative. Certification can also be obtained by viewing tutorial videos on our website (high speed connection required) and then successfully passing a short assessment test, which is also available through regular mail. All professionals involved in the inspection, review or certification of AES systems should also become Presby Certified.

8.4 Converging Flows Restriction

Systems must not be located where surface or ground waters will converge, causing surface water flow to become concentrated or restricted within the soil absorption field.

8.5 Daily Design Flow

Residential daily design flow for AES systems is calculated in accordance with State rules. The minimum daily design flow for any single-family residential system is two bedrooms and 200 GPD for any commercial system.

- a) Certain fixtures, such as jetted tubs, may require an increase in the size of the septic tank.
- b) Daily design flow for a single bedroom apartment with a kitchen connected to a residence (also sometimes referred to as a "studio" or "in-law apartment") shall be calculated by adding two additional bedrooms.
- c) When daily design flow is determined by water meter for commercial systems, refer to the State Rules.
- d) PEI recommends taking the average daily use from a peak month and multiply it by a peaking factor of 2 to 3 times.
- e) Note that "daily design flows" are calculated to assume occasional "peak" usage and a factor of safety; Systems are not expected to receive continuous dosing at full daily design load.

8.6 End-to-End Preferred Over Side-to-Side

If site conditions permit, End-to-End multiple bed configurations are preferable to Side-to-Side configurations (see para. 13.0, pg. 15).

8.7 Effluent (Wastewater) Strength

The AES pipe requirement for Bed or Trench systems is based on SPS 383.44(2)(a) strength wastewater, which has received primary treatment in a septic tank (see para. 8.13, pg. 10). Designing a system that will treat higher strength wastes may require additional AES pipe, septic tank volume and/or pretreatment. In these situations, consult our Technical Advisors at (800) 473-5298 for recommendations.

8.8 Filters, Alarms & Baffles

- a) Effluent Filters are **not** recommended for use with AES systems.
- b) If used, effluent filters must be maintained on at least an annual basis. Follow manufacturer's instructions regarding required inspections, cleaning and maintenance of the effluent filter. Please consult PEI for the most compatible filter recommendations.
- c) Effluent Filters must allow the free passage of air to ensure the proper functioning of the system. A blocked filter in any on-site septic system could interfere with venting, causing the system to convert to an anaerobic state and result in a shortened life.
- d) All pump systems to have a high-water alarm float or sensor installed inside the pump chamber.
- e) All septic tanks must be equipped with baffles to prevent excess solids from entering the system.
- f) Charcoal filters in vent stacks (for odor control) are not recommended by PEI. They can block air flow and potentially shorten system life. Contact PEI for recommendations to correct odor problems.

8.9 Flow Equalizers Required

All distribution boxes used to divide effluent flow require flow equalizers in their outlets. Flow equalizers are limited to a maximum of 15 GPM per equalizer.

8.10 Garbage Disposals (a.k.a. Garbage Grinders)

No additional AES pipe is required when using a garbage disposal (grinder). If a garbage disposal is utilized, follow the State's requirements regarding septic tank sizing. Multiple compartment septic tanks or multiple tanks are preferred and should be pumped as needed.

8.11 Maximum burial depth

Presby Environmental recommends AES systems be installed close enough to the surface to allow easy construction, however AES systems may be installed up to a maximum depth of 3 ft. to the top of the pipe. Consult Presby

Environmental Inc. for system greater than 3 ft. This is measured from the final grades down to the top of the AES pipes and components. Special safety and construction practices may be required by state, local and federal agencies for deeply constructed systems. Contact governing authorities prior to beginning construction.

8.12 Observation ports

All beds require at least two 4 in. diameter perforated Observation Ports wrapped with geo-textile fabric and installed at the bottom of the infiltrative surface (bed bottom – 12 in. below the AES pipe). For level beds, the ports are to be located at the ends and between the middle rows of the tall portion of the System Sand. For sloping beds, locate the ports at the lowest elevation and outer edges of the System Sand or System Sand extension if present. The ports must extend to final grade for easy access and have a threaded cap.

Illustration of Observation Port locations for level beds (number of rows may vary – row connections not shown):

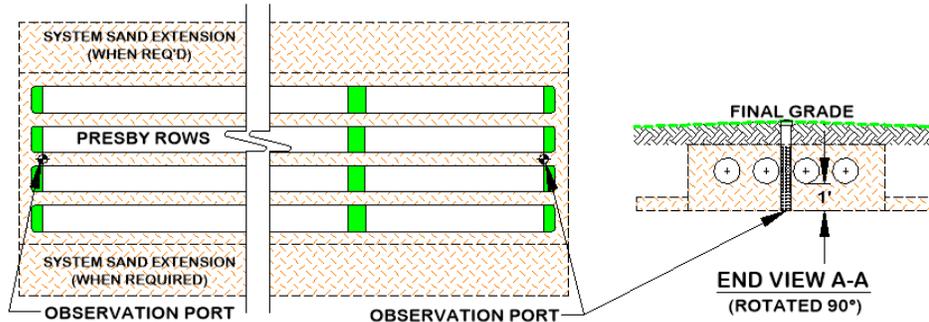

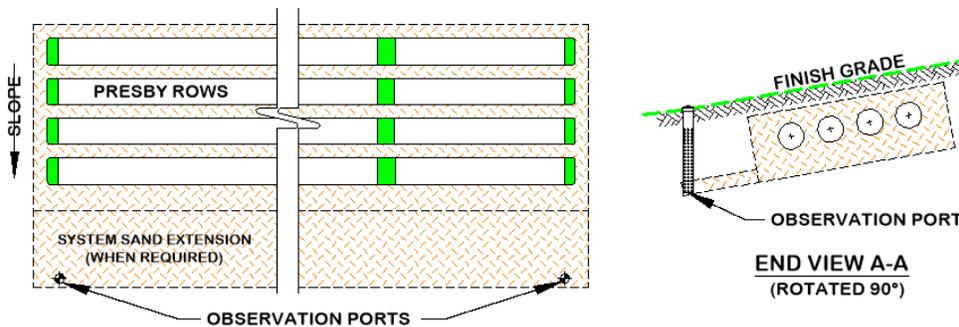

Illustration of Observation Port locations for sloping beds (number of rows may vary – row connections not shown):

8.13 Pipe Requirement

See para. 8.1, pg. 8 for additional Advanced Enviro-Septic® requirements. AES pipe requirements are as follows and require a 1.5 ft. minimum row spacing:

- a) Residential systems: 70 ft. per bedroom assuming monthly average effluent strength of 220 mg/L BOD₅ and 150 mg/L TSS
- b) Commercial systems: 2.14 GPD/ft. assuming monthly average effluent strength of 220 mg/L BOD₅ and 150 mg/L TSS
- c) Contact Presby Environmental, Inc. when treating high strength effluent.

8.14 Presby Environmental Standards and Technical Support

All systems must be designed and installed in compliance with the procedures and specifications described in this Manual and in the product's State approval. This Manual is to be used in conjunction with the State Department of Safety and Professional Services Administrative Rules. In the event of contradictions between this Manual and State regulations, Presby Environmental, Inc. should be contacted for technical assistance at (800) 473-5298.

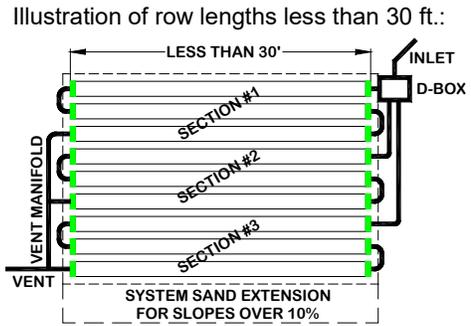

8.15 Pressure Distribution

The use of pressure distribution lines in AES systems is **prohibited**. Pumps may be utilized when necessary only to gain elevation and to feed a distribution box which then distributes effluent by gravity to the field.

8.16 Row Requirements

- a) All beds must have at least 2 rows.
- b) Maximum row length for any system is 100 ft.
- c) Recommended minimum row length is 30 ft.
- d) A combination (or D-box) distribution system must be used if any row length is less than 30 ft. The D-box must feed at least 30 ft. of AES pipe, a minimum of two D-box outlets must be used and the field must be vented.

- e) Row Center-to-Center Spacing is 1.5 ft. min. for all systems. Row spacing may be increased to accommodate greater basal area spacing requirements if desired.
- f) For level beds: the AES rows are centered in the middle of the System Sand bed area and any System Sand extensions divided evenly on both sides.
- g) For Sloping Beds: the elevations for each row must be provided on the drawing. All rows to be grouped at the high side of the System Sand bed area with any System Sand extensions placed entirely on the downslope side.
- h) All rows must be laid level to within +/- 1/2 in. (total of 1 in.) of the specified elevation and preferably should be parallel to the contour of the site.
- i) It is easier if row lengths are designed in exact 10 ft. increments since AES pipe comes in 10 ft. sections. However, if necessary, the pipe is easily cut to any length to meet site constraints.

8.17 Separation Distances (Horizontal and Vertical)

Separation distances to the seasonal high-water table (SHWT) or other restrictive features are measured from the outermost edge of the System Sand.

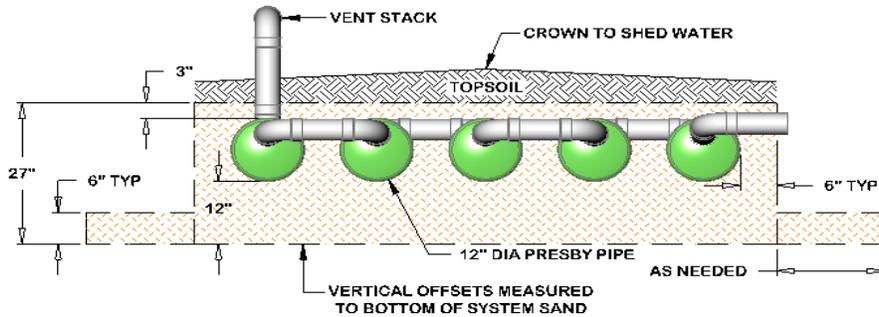

8.18 Sloping Sites and Sloping Systems

- a) The percentage of slope in all system drawings refers to the slope of the AES system, not the existing terrain ("site slope") and refers to the slope of the bed itself ("system slope").
- b) The system slope and the site slope do not have to be the same (see illustration in para.13.1, pg. 16).
- c) Maximum site slope is 33% and maximum system slope is 25%.

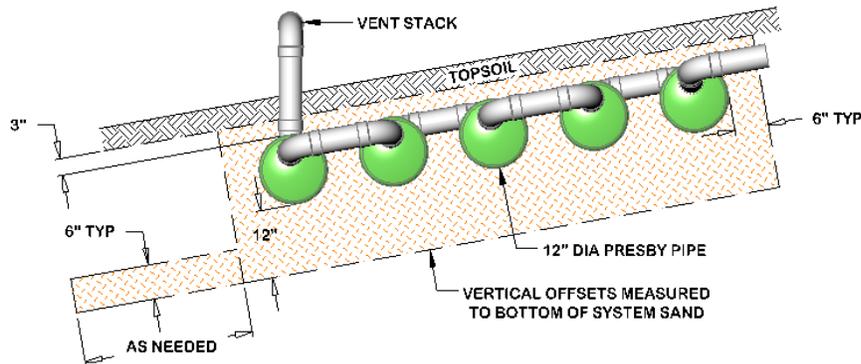

8.19 System Sand Bed Height Dimensions

The height of an AES Sand Bed measures 27 in. minimum (not including cover material):

- a) 12 in. minimum of System Sand below the AES pipe;
- b) 12 in. diameter of the pipe;
- c) 3 in. minimum of System Sand above the AES pipe; and
- d) When System Sand Extensions are required, they must be a minimum of 6 in. thick (see illustration below – observation ports not shown).

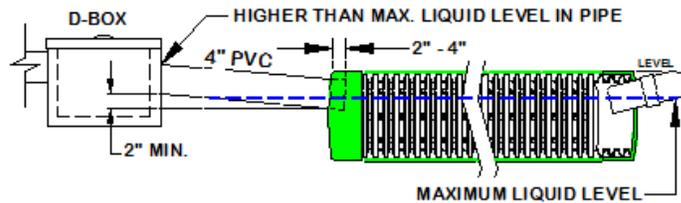

- e) Sloping systems require any System Sand extension to be placed on the downslope side of the field. If the system slope is over 10% the sand extension must be at least 2.5 ft. (see illustration below – observation ports not shown).

8.20 Two Inch Rule

The outlet of a septic tank or distribution box (if used) must be set at least 2 in. above the highest inlet of the AES row, with the connecting pipe slope not less than 1% (approximately 1/8 in. per foot.) See illustration of 2-inch rule below:

8.21 Topographic Position Requirement

The system location must be located in an area that does not concentrate water, both surface and subsurface. If allowed by State and local authorities, altering the terrain upslope of a system may alleviate this requirement if the waters are sufficiently altered to redirect flows away from the field.

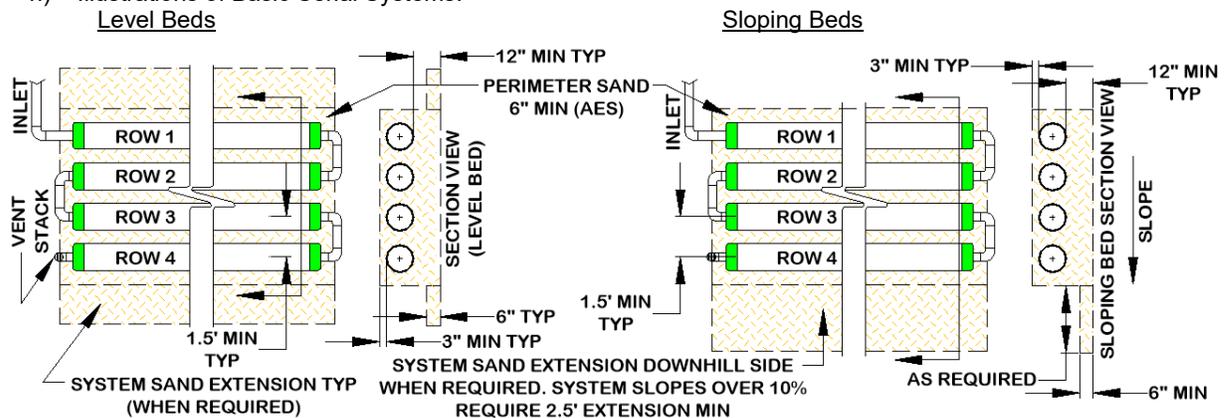

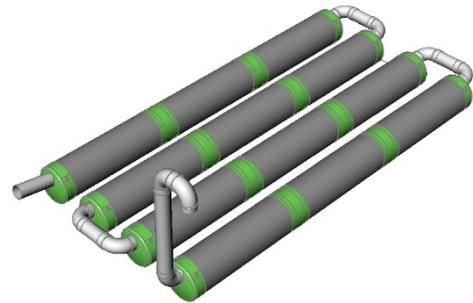

8.22 Water Purification Systems

- Water purification systems and water softeners should **not** discharge into any AES system. This “backwash” does not require treatment and the additional flow may overload the system.
- If there is no alternative means of disposing of this backwash other than in the system, then the system will need to be “oversized.” Calculate the total amount of backwash in GPD, multiply by 3, and add this amount to the daily design flow when determining the field and septic tank sizing.
- Water purification systems and water softeners require regular routine maintenance; consult and follow the manufacturer’s maintenance recommendations.

9.0 Basic Serial Distribution

AES rows are connected in series at the ends with raised connections, using offset adapters. Basic Serial distribution systems are quick to develop a strong biomat in the first row, provide a longer flow route, improved effluent treatment and ensure air will pass through all the AES rows. Other criteria:

- May be used for single beds of 750 GPD or less.
- Incorporates rows in serial distribution in a single bed.
- Maximum length of any row is 100 ft.
- Flow Equalizers are not required for Basic Serial systems.
- For level beds: any required System Sand extension is to be evenly divided and placed on both sides of the AES pipes.
- For sloping beds, any required System Sand extension is placed entirely on the downhill (low) side of the field. If the bed slopes over 10%, the System Sand extension must be at least 2.5 ft.
- Gravity fed Basic Serial systems do not require the use of a D-box (fed directly from the septic tank).
- Illustrations of Basic Serial Systems:

9.1 Basic Serial Configuration with Unusual Shapes:

Bed may be constructed with unusual shapes to avoid site obstacles or meet setback requirements.

Trapezoidal:

Parallelogram:

10.0 Bottom Drain

A bottom drain is a line connected to the hole in the 6 o'clock position of a double offset adapter at the end of each serial section or each row in a D-box Distribution or Combination Configuration which drains to a sump and is utilized to lower the water level in a saturated system or to facilitate system rejuvenation. System may only be drained by a licensed wastewater hauler/pumper pumping effluent from the bottom drain. There must be 18 in. from the bottom of the sump to the bottom of the drain. The sump should be brought above the final grade and have a locking or mechanically fastened cover.

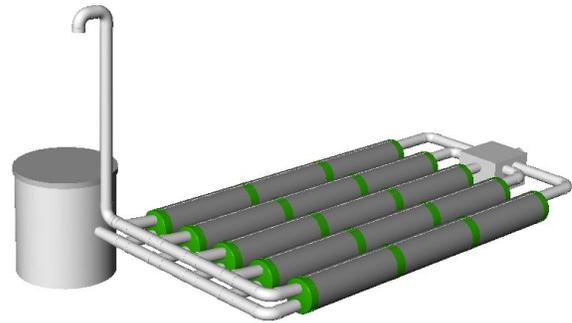

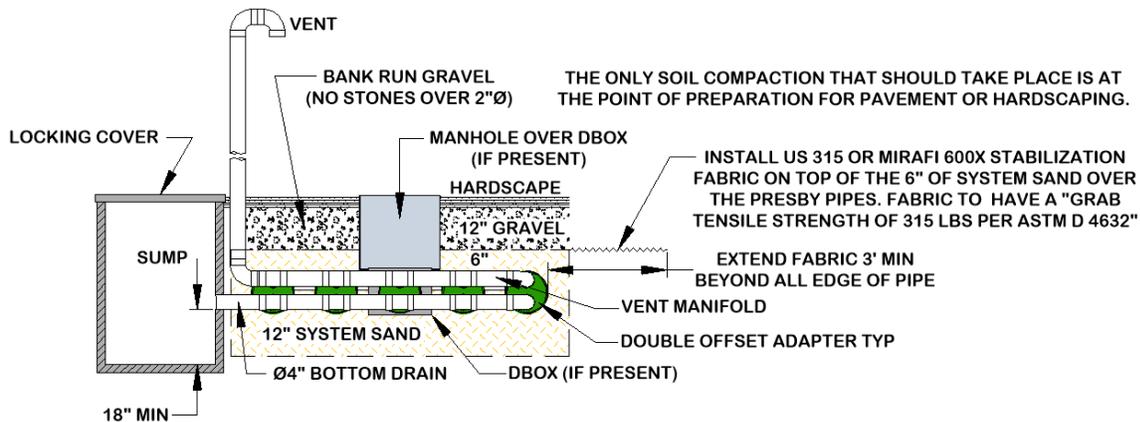

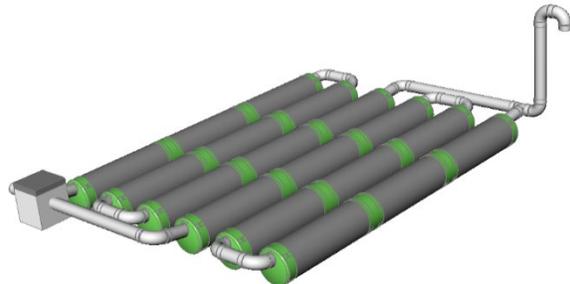

Illustration of a bottom drain used for an H-20 loaded system (End View):

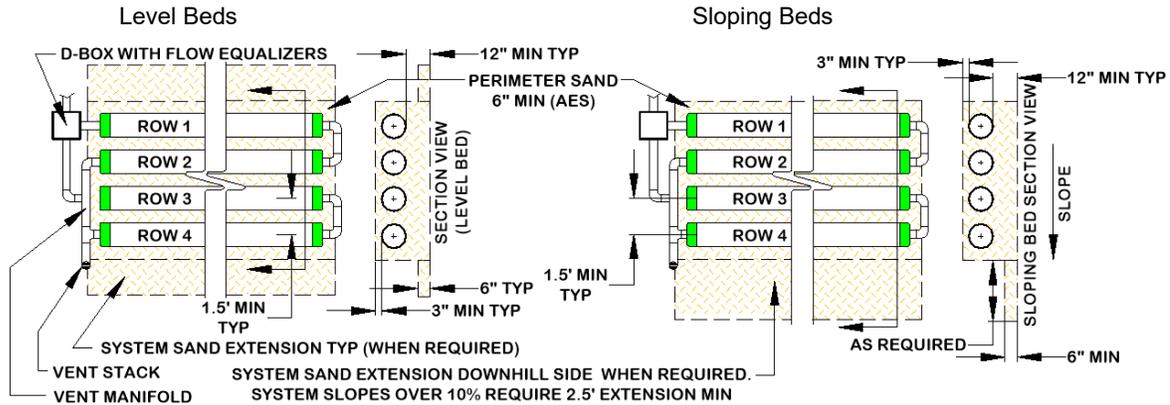

11.0 Combination Serial Distribution

Combination Serial distribution within one bed, or multiple beds, is required for systems with daily design flows greater than 750 GPD. Combination Serial distribution is quick to develop a strong biomat in the first row of each section, providing improved effluent treatment. Each Combination Serial section is limited to a maximum loading of 750 gallons/day.

- Combination Serial distribution consists of two or more serial sections installed in a single bed.
- Each section in a Combination Serial system consists of a series of AES rows connected at the ends with raised connections, using offset adapters and PVC sewer and drainpipe.
- Maximum length of any row is 100 ft.
- There is no limit on the number of Combination Serial Sections within a bed.
- For level beds: any required System Sand extension is to be evenly divided and placed on both sides of the pipes.
- For sloping beds, any required System Sand extension is placed entirely on the downhill (low) side of the field. If the bed slopes over 10%, the System Sand extension must be at least 2.5 ft.

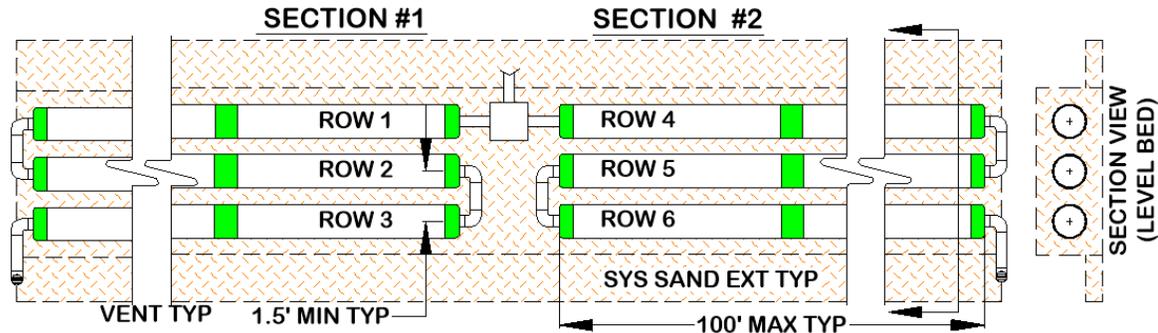

- g) When the vent manifold is on the same side as the serial section inlets, the manifold runs over the top of these inlets (as shown below).
- h) Combination systems require the use of an adequately sized D-box.
- i) Illustrations of Combination Serial Systems:

11.1 Butterfly Configuration

- a) A "butterfly configuration," is considered a single bed system with two or more sections (can also be D-box or Combination configurations).
- b) Maximum length of any row is 100 ft.
- c) Serial Section loading limit is 750 GPD.
- d) Beds can contain any number of serial sections.
- e) For level beds: any required System Sand extension is to be evenly divided and placed on both sides of the pipes.
- f) For sloping beds: any required System Sand extension is placed entirely on the downhill (low) side of the field. If the bed slopes over 10%, the System Sand extension must be at least 2.5 ft.
- g) Illustration of a level bed Butterfly configuration (plan view):

11.2 Section Loading

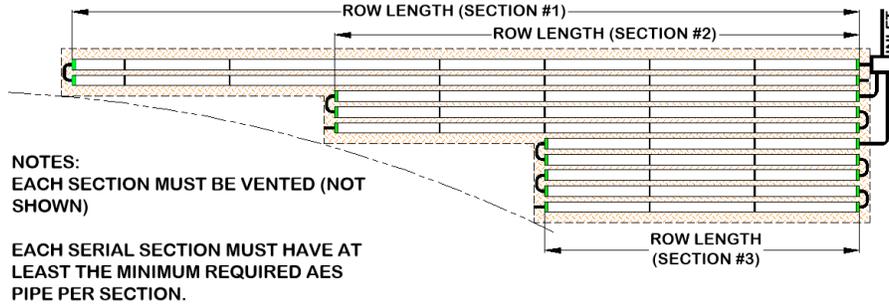

Each section in a Combination Serial system has a maximum daily design flow of 750 GPD. More than the minimum number of sections may be used. Ex: Daily design flow = 1,000 GPD requires $(1,000 \div 750) = 1.4$, use 2 sections minimum. Combination systems are only required if the daily design flow exceeds 750 GPD.

11.3 Section Length Requirement

- a) Each section must have the same minimum linear feet of pipe.
- b) The minimum linear feet of pipe per section is determined by dividing the total linear feet required in the AES system by the number of sections required.
- c) A section may exceed the minimum linear feet required.
- d) Rows within a section may vary in length to accommodate site constraints.

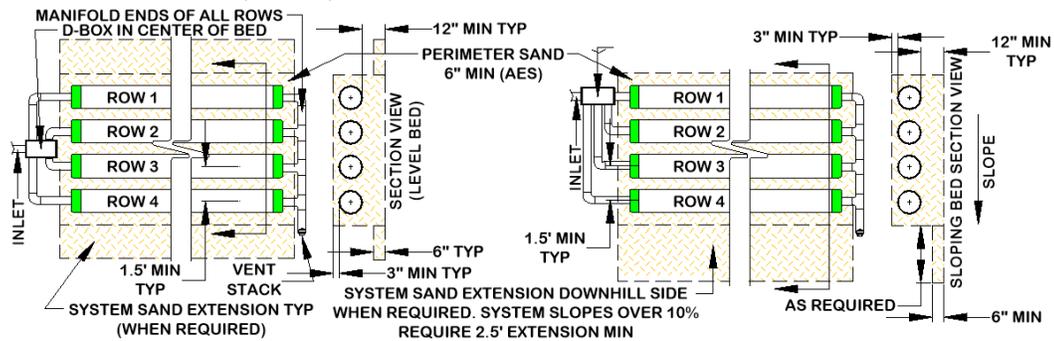

11.4 Irregular Shaped Combination Serial Configuration

Illustration of Irregular shaped combination system (venting not shown):

12.0 D-box Distribution

- All rows in this configuration must be the same length.
- Flow equalizers must be used in the D-box.
- Use a Manifold to connect the ends of all rows. Manifold to be sloped toward AES pipes.
- Maximum row length is 100 ft.
- Place the D-box on level, firmly compacted soil.
- All rows must be laid level end-to-end.
- A 2 in. min. drop is required between the D-box outlets and the AES pipe inlets.
- For level beds: any required System Sand extension is to be evenly divided and placed on both sides of the AES pipes.
- For sloping beds: any required System Sand extension is placed entirely on the downhill (low) side of the field. If the bed slopes over 10%, the System Sand extension must be at least 2.5 ft.
- Illustrations for D-box (Parallel) Distribution:

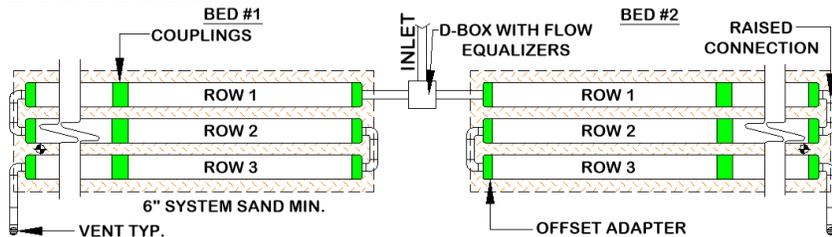

13.0 Multiple Bed Distribution

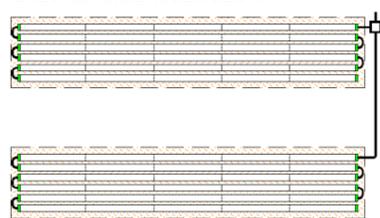

Multiple Bed distribution incorporates two or more beds, each bed with Basic Serial, Combination Serial, or D-box distribution, and each receiving an equal amount of effluent from a D-box. Multiple beds may be oriented along the contour of the site or along the slope of the site.

- Each bed must have the same minimum linear feet of pipe. The minimum linear feet of pipe per bed is determined by dividing the total linear feet required in the AES system by the number of beds.
- Rows within a bed may vary in length to accommodate site constraints, except with D-box configuration which requires all rows to be the same length.
- End-to-End configurations are preferred to Side-to-Side configurations.
- In Side-to-Side configuration, one bed is placed beside another or one bed is placed down slope of another. Bed separation distance is measured from pipe-to-pipe and is dependent on soil hydrology and State requirements.

End-to-End Illustration:

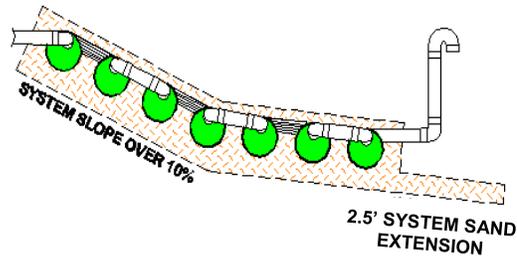

Side-to-Side Illustration:

13.1 System Sand Extension

In systems where SSBA is greater the PLW + 1' (see para. 7.0, pg. 6, step #9). In systems sloping more than 10%, a 2.5 ft. minimum System Sand extension is required. The System Sand extension area is placed on the down slope side of all sloping systems. For level systems, the System Sand Extension is divided equally and placed on both sides. The System Sand extension area is a minimum of 6 in. deep. For beds with multiple slopes, if any portion of the bed has a system slope greater than 10% a system sand extension is required. Illustration of bed with multiple slopes below.

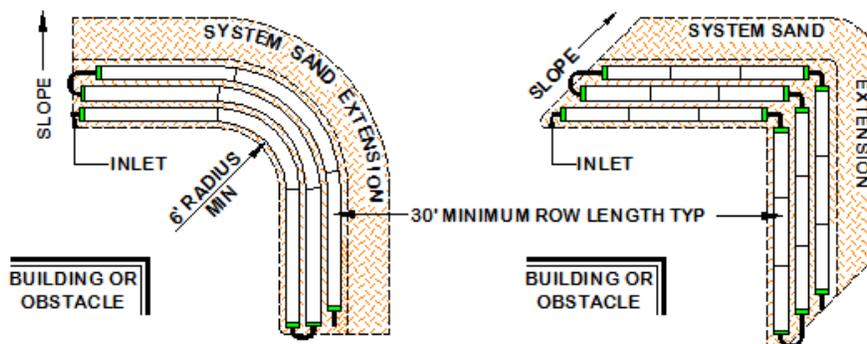

13.2 Total Linear Feet Requirement

- Maximum row length is 100 ft.
- Each section or bed must have at least the minimum linear feet of pipe (total feet of pipe required divided by number of sections equals the minimum number of feet required for each section or bed).
- A section or bed may exceed the minimum linear length.
- Rows within a section or bed may vary in length (except D-box configurations) to accommodate site constraints.

14.0 Angled and Curving Beds

Angled configurations are used to avoid obstacles.

- Rows should follow the contour of the site as much as possible
- Rows are angled by bending pipes up to 90 degrees or through the use of offset adapters
- Row lengths are required to be a minimum of 30 ft.
- Illustrations of Angled Beds:

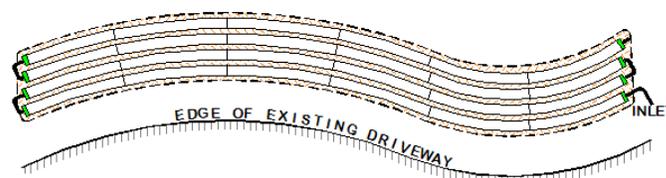

14.1 Trench Systems

AES pipe may be installed in trench configurations on level or sloping terrain and may utilize serial, combination or parallel distribution. Trench systems may incorporate one or two rows of AES pipe. A minimum of 12 in. below, 6 in. between and around the perimeter and 3 in. above of System Sand are required for all AES systems. Consult regulatory rules for required trench separation.

15.0 Curved Beds

Curved configurations work well around structures, setbacks, and slopes. Multiple curves can be used within a system to accommodate various contours of the site.

16.0 Non-Conventional System Configurations

Non-conventional system configurations may have irregular shapes to accommodate site constraints.

17.0 H-20 Loading

H-20 is a specification created by the American Association of State Highway Transportation Officials (AASHTO), which limits axle and wheel loading under this designation. If a system is to be installed below an area that will be subjected to vehicular traffic (H-20), it must be designed and constructed as depicted in para. 10.0 in order to protect the system from compaction and/or damage. Note that a layer of stabilization fabric is added between the System Sand and the cover material. All H-20 systems require venting. See para. 10.0, pg. 13 for illustration of H-20 loading requirements.

18.0 Pumped System Requirements

Pumped systems supply effluent to the system using a pump and distribution box when site conditions do not allow for a gravity system. Dosing siphons are also an acceptable means of delivering effluent to the system.

18.1 Alarm

States require all pump systems to have a high-water alarm float or sensor installed inside the pump chamber.

18.2 Differential Venting

All pump systems must use differential venting (see illustration, para. 20.2, pg. 18).

18.3 Distribution Box

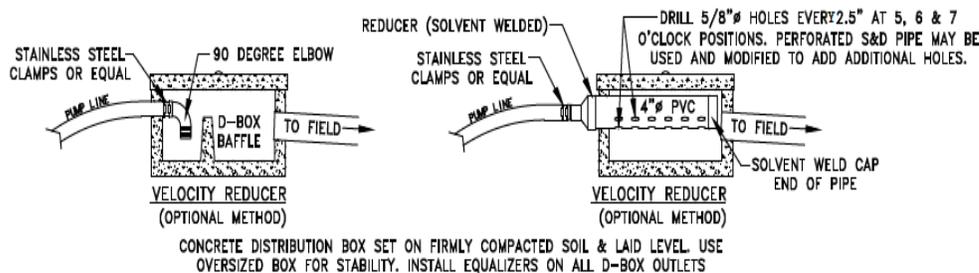

All pump systems require a distribution box with some means of velocity reduction for the effluent entering the D-box.

18.4 Velocity Reduction

The rate at which effluent enters the AES pipe must be controlled. Excessive effluent velocity can disrupt solids that settle in the pipes.

- Effluent must never be pumped directly into AES pipe.
- A distribution box or tank must be installed between the pumping chamber and the AES pipe to reduce effluent velocity.
- Force mains must discharge into a distribution box (or equivalent) with velocity reducer and a baffle, 90° bend, tee or equivalent (see illustrations).

Two methods of velocity reduction:

18.5 Dose Volume

- Pump dosing should be designed for a minimum of 6 cycles per day.
- If possible, the dosing cycle should provide one hour of drying time between doses.

18.6 Basic Serial Distribution Limit

Pumped systems with Basic Serial distribution are limited to a maximum dose rate of 40 gallons per minute and do not require the use of a flow equalizer on the D-box outlet. Never pump directly into AES pipe.

18.7 Combination and Multiple-Bed Distribution Limit

All systems with Combination Serial distribution or Multiple Bed distribution must use Flow Equalizers in each distribution box outlet. Each Bed or section of Combination Serial distribution is limited to a maximum of 15 gallons per minute, due to the flow constraints of the equalizers. Example: pumping to a combination system with 3 sections (using 3 D-box outlets). The maximum delivery rate is $(3 \times 15) = 45$ GPM. Always provide a means of velocity reduction.

19.0 System Sand and Sand Fill Requirements for All Beds

It is critical to the proper functioning of AES systems that the proper amount and type of System Sand be installed.

19.1 Quantity of System Sand

System Sand is placed a minimum of 12 in. below, 3 in. above and 6 in. between the AES rows and a minimum of 6 in. horizontally around the perimeter of the AES rows.

19.2 Sand Fill

Sand fill meeting ASTM C-33 or equivalent requirements is used to raise the elevation of the system in order to meet the required separation distance from the SHWT or other restrictive feature. No organic material or stones larger than 6 in. are allowed in the sand fill. System Sand may be used in place of sand fill; however, this may increase material costs.

20.0 Venting Requirements

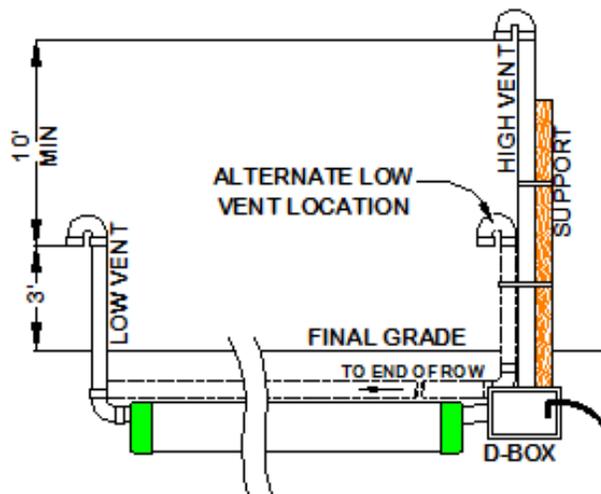

An adequate air supply is essential to the proper functioning of AES systems. Venting is always required. Pump systems must utilize Differential Venting.

20.1 General Rules

- Vent openings must be located to ensure the unobstructed flow of air through the entire system.
- The low vent inlet must be a minimum of 1 ft. above final grade or anticipated snow level, whichever is greater.
- One 4 in. vent is required for every 1,000 ft. of AES pipe.
- A single 6 in. vent may be installed in place of up to three 4 in. vents.
- If a vent manifold is used, it must be at least the same diameter as the vent(s).
- When venting multiple beds, it is preferred that each bed be vented separately rather than manifolding bed vents together.
- Schedule 40 PVC or equivalent should be used for all vent stacks.
- Remote Venting may be utilized to minimize the visibility of vent stacks.

20.2 Differential Venting

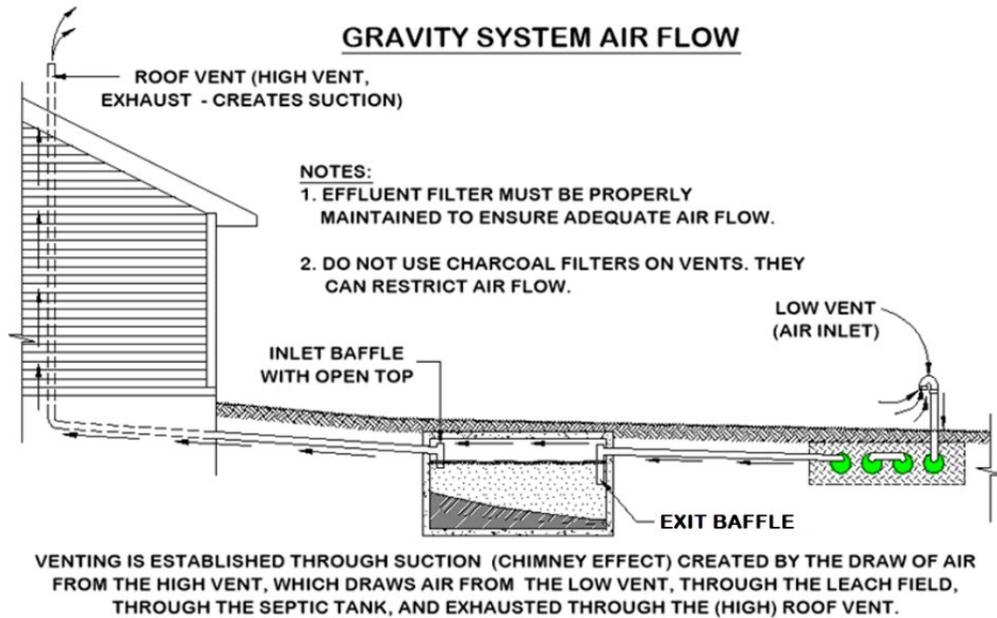

- Differential venting is the use of high and low vents in a system.
- In a gravity system, the roof stack acts as the high vent.
- High and low vent openings must be separated by a minimum of 10 vertical ft.
- If possible, the high and low vents should be of the same capacity.

20.3 Vent Locations for Gravity Systems

- A low vent is installed at the end of the last row of each section or the end of the last row in a Basic Serial bed, or at the end of each row in a D-box Distribution Configuration system. A vent manifold may be used to connect the ends of multiple sections or rows.
- The house (roof) vent functions as the high vent as long as there are no restrictions or other vents between the low vent and the house (roof) vent.
- When the house (roof) vent functions as the high vent, there must be a minimum of a 10 ft. vertical differential between the low and high (roof) vent openings.

d) Illustration of gravity system air flow:

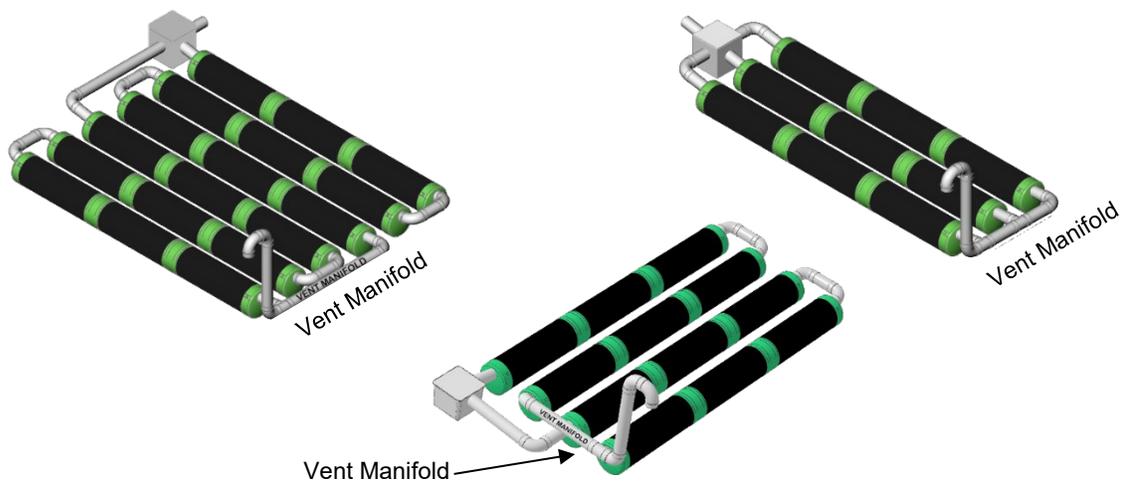

20.4 Pump System Vent Locations

- a) A low vent is installed through an offset adapter at the end of each section, Basic Serial bed or attached to a vent manifold.
- b) A high vent is attached to an unused distribution box outlet.
- c) A 10 ft. minimum vertical differential is required between high and low vent openings.
- d) When venting multiple beds, it is preferred that each bed be vented separately (have their own high and low vents) rather than manifolding bed vents together.
- e) The Low and High vents may be swapped provided the distribution box is insulated against freezing in cold climates.
- f) See Remote Venting (para. 20.7, pg. 20) and By-pass Venting (para. 20.8, pg. 20) for options to relocate or eliminate the High Vent.

20.5 Vent Manifolds

A vent manifold may be incorporated to connect the ends of a number of sections or rows of AES pipe to a single vent opening. Slope the lines connecting the manifold to the AES pipes to drain condensation. See illustrations of vent manifolds below:

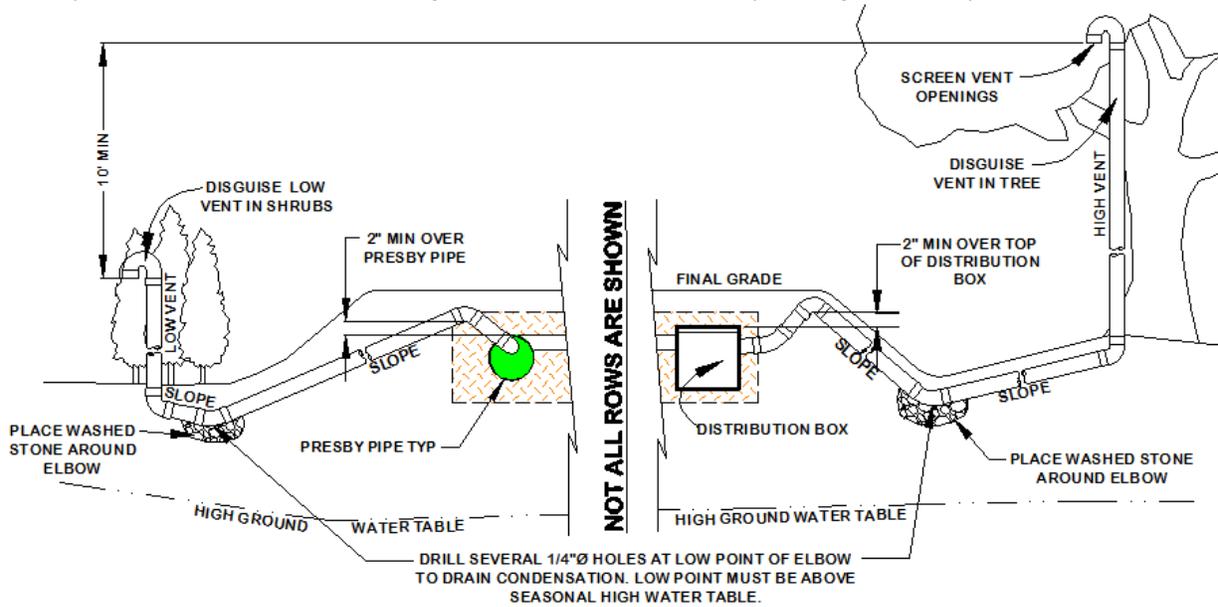

20.6 Vent Piping Slope

Vent piping should slope downward toward the system to prevent moisture from collecting in the pipe and blocking the passage of air.

20.7 Remote Venting

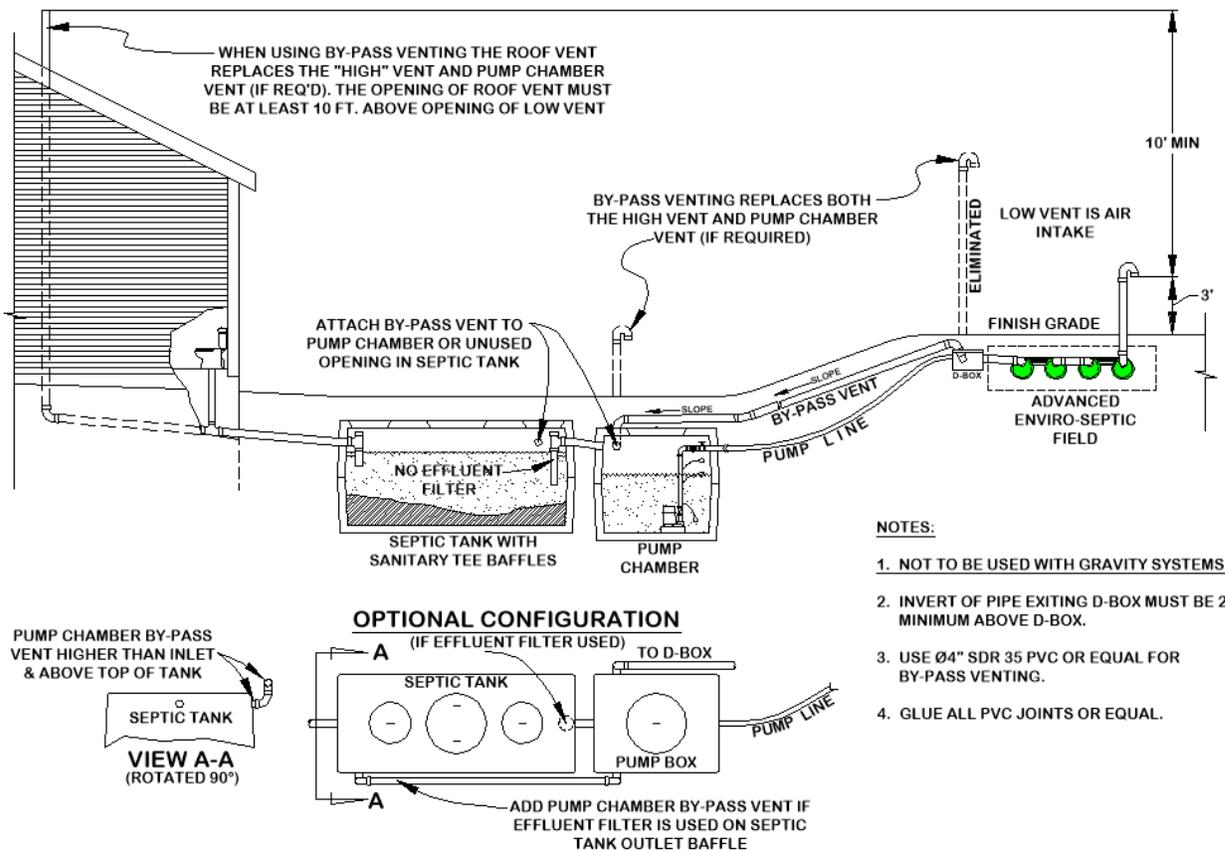

If site conditions do not allow the vent pipe to slope toward the system, or the owner chooses to utilize remote venting for aesthetic reasons (causing the vent pipe not to slope toward the system), the low point of the vent line must be drilled creating several 1/4 in. holes to allow drainage of condensation. This procedure may only be used if the vent pipe connecting to the system has:

- A **high point** that is above the highest point of all AES pipes or the Distribution Box; and,
- A **low point** opened for drainage which is above the SHWT. (See diagram below.)

20.8 By-Pass Venting

BY-PASS VENTING

21.0 Site Selection

21.1 Determining Site Suitability

Refer to State or local rules regarding site suitability requirements.

21.2 Topography

Locate systems on convex, hill, slope or level locations that do not concentrate surface flows. Avoid swales, low areas, or toe-of-slope areas that may not provide sufficient drainage away from the system.

21.3 Surface Water Diversions

Surface water runoff must be diverted away from the system. Diversions must be provided up-slope of the system and designed to avoid ponding. Systems must not be located in areas where surface or groundwater flows are concentrated.

21.4 Containment

Systems should not be located where structures such as curbs, walls or foundations might adversely restrict the soil's ability to transport water away from the system.

21.5 Hydraulic loading

Systems should not be located where lawn irrigation, roof drains, or natural flows increase water loading to the soils around the system.

21.6 Access

Systems should be located to allow access for septic tank maintenance and to at least one end of all AES rows. Planning for future access will facilitate rejuvenation in the unlikely event the system malfunctions.

21.7 Landscaping

Seeding/planting of vegetative cover must be with shallow rooting plants. No trees or shrubs should be located within 10 ft. of the system to prevent root infiltration.

21.8 Replacement System

In the event of system malfunction, contact PEI for technical assistance prior to attempting Rejuvenation procedures.

In the unlikely event that a system needs to be replaced ...

- a) It can be reinstalled in the same location, eliminating the need for a replacement field reserve area.
- b) All unsuitable material must be removed prior to replacement system construction.
- c) Disposal of hazardous materials to be in accordance with State and local requirements.
- d) Permits may be required for system replacement; contact the appropriate local or state agency.

22.0 Installation Requirements, Component Handling and Site Preparation

22.1 Component Handling

- a) Keep mud, grease, oil, etc. away from all components.
- b) Avoid dragging pipe through wet or muddy areas.
- c) Store pipe on high and dry areas to prevent surface water and soil from entering the pipes or contaminating the fabric prior to installation.
- d) The outer fabric of the AES pipe is ultra-violet stabilized; however, this protection breaks down after a period of time in direct sunlight. To prevent damage to the fabric, cover the pipe with an opaque tarp if stored outdoors.

22.2 Critical Reminder to Prevent Soil Compaction

It is critical to keep excavators, backhoes, and other equipment off the excavated or tilled surface of a bed. Before installing the System Sand, excavation equipment should be operated around the bed perimeter; not on the bed itself.

22.3 Site Preparation Prior to Excavation

- a) Locate and stake out the System Sand bed, extension areas and soil material cover extensions on the site according to the approved plan.
- b) Install sediment/erosion control barriers prior to beginning excavation to protect the system from surface water flows during construction.
- c) Do not travel across or locate excavation equipment within the portion of the site receiving System Sand.
- d) Do not stockpile materials or equipment within the portion of the site receiving System Sand.
- e) It is especially important to avoid using construction equipment down slope of the system to prevent soil compaction.

22.4 When to Excavate

- a) Do not work wet or frozen soils. If a fragment of soil from about 9 in. below the surface can easily be rolled into a wire, the soil moisture content is too high for construction.
- b) Do not excavate the system area immediately after, during, or before precipitation.

22.5 Tree Stumps

Remove all tree stumps and the central root system below grade by using a backhoe or excavator with a mechanical "thumb" or similar extrication equipment, lifting or leveraging stump in a manner that minimizes soil disturbance.

- a) Do not locate equipment within the limits of the System Sand bed.
- b) Avoid soil disturbance, relocation, or compaction.
- c) Avoid mechanical leveling or tamping of dislodged soil.
- d) Fill all voids created by stump or root removal with System Sand.

22.6 Organic Material Removal

Before tilling, remove all grass, leaves, sticks, brush and other organic matter or debris from the excavated system site. It is not necessary for the soil of the system site to be smooth when the site is prepared.

22.7 Raking and Tilling Procedures

All areas receiving System Sand, sand fill and fill extensions **must** be raked or tilled. If a backhoe/excavator is used to till the site, fit it with chisel teeth and till the site. The backhoe/excavator must remain outside of the proposed System Sand area and extensions. For in-ground bed systems, excavate the system bed as necessary below original grade. Using an excavator or backhoe, tilt the bucket teeth perpendicular to the bed and use the teeth to rake furrows 2 – 6 in. deep into the bottom of the entire area receiving System Sand or sand fill ("receiving area").

22.8 Install System Sand and/or Sand Fill Immediately After Excavation

- a) To protect the tilled area (System Sand bed area and System Sand extension area) from damage by precipitation, System Sand should be installed immediately after tilling.
- b) Work off either end or the uphill side of the system to avoid compacting soil.
- c) Keep at least 6 in. of sand between the vehicle tracks and the tilled soil of the site if equipment must work on receiving soil.
- d) Track construction equipment should not travel over the installed system area until at least 12 in. of cover material is placed over the AES pipes.
- e) Heavy equipment with tires must never enter the receiving area due to likely wheel compaction of underlying soil structures.

22.9 Distribution Box Installation

To prevent movement, be sure D-boxes are placed level on compacted soil, sand, pea gravel base, or concrete pad.

22.10 Level Row Tolerances

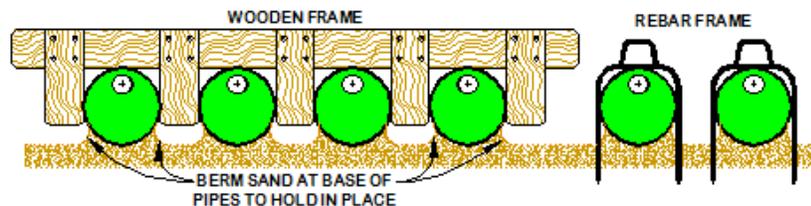

Use a laser level or transit to install rows level. Variations beyond 1 in. ($\pm 1/2"$) may affect system performance and are not acceptable.

22.11 Correct Alignment of AES Bio-Accelerator[®] Fabric

The Bio-Accelerator (white geo-textile fabric) is to be positioned centered along the bottom of the pipe rows (sewn seam up).

22.12 Row Spacers

System Sand may be used to keep pipe in place while covering, but simple tools may also be constructed for this purpose. Two examples are shown. One is made from rebar, the other from wood. Center-to-center row spacing may be larger than specified by this manual. **Caution:** Remove all tools used as row spacers before final covering.

22.13 Connect Rows Using Raised Connections

Raised connections consist of offset adapters, 4 in. PVC sewer and drainpipe, and 90° elbows. They enable greater liquid storage capacity and increase the bacterial surfaces being developed. Use raised connections to connect the rows of the system (see para. 3.8, pg. 4). Glue or mechanically fasten all pipe connections.

22.14 Backfilling Rows

- a) Spread System Sand between the rows.
- b) Confirm pipe rows are positioned with Bio-Accelerator along the bottom (sewn seam up).
- c) Straddle each row of pipe and walk heel-to-toe its entire length, ensuring that System Sand fills all void spaces beneath the pipe.
- d) Finish spreading System Sand to the top of the rows and leave them exposed for inspection purposes.

22.15 Backfilling and Final Grading

Spread System Sand to a minimum of 3 in. over the pipe and a minimum of 6 in. beyond AES pipes on all four sides beyond the AES pipes. Spread soil material free of organics, stones over 4 in. and building debris, having a texture similar to the soil at the site, without causing compaction. Construction equipment should not travel over the installed system area until at least 12 in. of cover material is placed over the AES pipes (H-10 Loading). 18 in. of cover material over the AES system is required for H-20 loading (see para. 17.0, pg. 17).

22.16 System Soil Cover Material

A minimum of 12 in. of suitable earth cover (topsoil or loam), with a texture similar to the soil at the site and capable of sustaining plant growth, must be placed above the installed system.

22.17 Erosion Control

To prevent erosion, soil cover above the system shall be planted with native, shallow-rooted vegetation such as grass, wildflowers and certain perennials or ground covers.

22.18 Trees and Shrubs

It is recommended that no trees or shrubs be located within 10 ft. of the system perimeter to prevent roots from growing into and damaging the system.

23.0 System Bacteria Rejuvenation and Expansion

This section covers procedures for bacteria rejuvenation and explains how to expand existing systems.

Note: Presby Environmental, Inc. must be contacted for technical assistance prior to attempting rejuvenation procedures.

23.1 Why would System Bacteria Rejuvenation be needed?

Bacteria rejuvenation is the return of bacteria to an aerobic state. Flooding, improper venting, alteration or improper depth of soil material cover, use of incorrect sand, sudden use changes, introduction of chemicals or medicines, and a variety of other conditions can contribute to converting bacteria in any system from an aerobic to an anaerobic state. This conversion severely limits the bacteria's ability to effectively treat effluent, as well as limiting liquids from passing through. A unique feature of the AES system is its ability to be rejuvenated in place.

23.2 How to Rejuvenate System Bacteria

System bacteria are "rejuvenated" when they return to an aerobic state. By using the following procedure, this can be accomplished in most systems without costly removal and replacement.

1. Contact Presby Environmental before attempting Rejuvenation for technical assistance.
2. Determine and rectify the problem(s) causing the bacteria conversion.
3. Drain the system by excavating one end of all the rows and removing the offset adapters or pump the system using the Bottom Drain (if present).
4. If foreign matter has entered the system, flush the pipes with a garden hose.
5. Safeguard the open excavation.
6. Guarantee a passage of air through the system.
7. Allow all rows to dry for 72 hours minimum. The System Sand should return to its natural color.
8. Re-assemble the system to its original design configuration. As long as there is no physical damage to the AES components, the original components may be reused.

24.0 System Expansion

AES systems are easily expanded by adding equal lengths of pipe to each row of the original design or by adding additional equal sections. All system expansions must comply with State and local regulations. Permits may be required prior to system expansion.

24.1 Reusable Components

AES pipe and components are not biodegradable and may be reused. In cases of improper installation, it may be possible to excavate, clean, and reinstall all system components.

25.0 Operation & Maintenance

25.1 Proper Use

AES systems require minimal maintenance, provided the system is not subjected to abuse. An awareness of proper use and routine maintenance will guarantee system longevity. We encourage all system owners and service providers to obtain and review a copy of our Owner's Manual, available from our website www.PresbyEnvironmental.com or via mail upon request to (800) 473-5298 or info@presbyeco.com.

25.2 System Abuse Conditions

The following conditions constitute system abuse:

- a) Liquid in high volume (excessive number of occupants and use of water in a short period of time, leaking fixtures, whirlpool tubs, hot tubs, water softening equipment or additional water discharging fixtures if not specified in system design).
- b) Solids in high volume (excessive number of occupants, paper products, personal hygiene products, garbage disposals or water softening equipment if not specified in system design)
- c) Antibiotics and medicines in high concentrations
- d) Cleaning products in high concentrations
- e) Fertilizers or other caustic chemicals in any amount
- f) Petroleum products in any amount
- g) Latex and oil paints
- h) System suffocation (compacted soils, barrier materials, etc.) without proper venting

Note: PEI and most regulatory agencies do not recommend the use of septic system additives.

25.3 System Maintenance/Pumping of the Septic Tank

- a) Inspect the septic tank at least once every three years under normal usage.
- b) Pump the tank when surface scum and bottom sludge occupy one-third or more of the liquid depth of the tank.
- c) If a garbage disposal is used, the septic tank will likely require more frequent pumping.
- d) After pumping, inspect the septic tank for integrity to ensure that no groundwater is entering it. Also, check the integrity of the tank inlet and outlet baffles and repair if needed.
- e) Inspect the system to ensure that vents are in place and free of obstructions.
- f) Effluent filters require ongoing maintenance due to their tendency to clog and cut off oxygen to the System. Follow filter manufacturer's maintenance instructions and inspect filters frequently.
- g) Provide all system maintenance records to County inspector at each three-year county level inspection.

25.4 Site Maintenance

It is important that the system site remain free of shrubs, trees, and other woody vegetation, including the entire System Sand bed area, and areas impacted by side slope tapering. Roots can infiltrate and cause damage or clogging of system components

26.0 Glossary

This Manual contains terminology which is common to the industry and terms that are unique to AES systems. While alternative definitions may exist, this section defines how these terms are used in this Manual.

26.1 Advanced Enviro-Septic® (AES) Pipe

A single unit comprised of corrugated plastic pipe, Bio-Accelerator® fabric along its bottom which is surrounded by a layer of randomized plastic fibers and a sewn geo-textile fabric. Each unit is 10 ft. in length, with an outside diameter of 12 in. and a storage capacity of approximately 58 gallons. Each ft. of AES provides over 40 sq. ft. of total surface area for bacterial activity. The sewn seam is always oriented up (12 o'clock position) within the bed. A white tag is sewn into the seam indicating the product is AES pipe. Pipes are joined together with couplings to form rows. AES is a combined wastewater treatment and dispersal system.

26.2 Basic Serial Distribution

Basic Serial distribution incorporates AES rows in serial distribution in a single bed (see Basic Serial Distribution, para. 9.0, pg. 12).

26.3 Bio-Accelerator®

Bio-Accelerator fabric screens additional solids from the effluent, enhances and accelerates treatment, facilitates quick start-up after periods of non-use, provides additional surface area for bacterial growth, promotes even distribution, and further protects outer layers and the receiving surfaces so they remain permeable. Bio-Accelerator is only available with AES.

26.4 Bottom Drain

A bottom drain is a line connected to the hole in the 6 o'clock position of a double offset adapter at the end of each serial section or each row in a D-box Distribution Configuration which drains to a sump and is utilized to lower the water level in a saturated system or to facilitate system rejuvenation (see illustration, para. 10.0, pg. 13).

26.5 Butterfly Configuration

A variation of a standard, single bed system with the D-box located in the center, with rows oriented symmetrically on either side, and with each side or section receiving an equal volume of flow from the D-box. See Butterfly Configuration (see para. 11.1, pg. 14).

26.6 Center-to-Center Row Spacing

The distance from the center of one AES row to the center of the adjacent row. (C/L) as referenced in Table C represents the Center Line for Center-to-Center Row Spacing.

26.7 Coarse Randomized Fiber

A mat of coarse, randomly-oriented fibers which separates more suspended solids from the effluent protecting the bacterial surface in the geo-textile fabric (see illustration, para. 2.0, pg. 2).

26.8 Combination Serial Distribution

Incorporates two or more sections of AES pipe in a single bed, with each section receiving a maximum of 750 GPD of effluent from a distribution box. Combination Distribution is not required for daily flows of 750 GPD or less. See Combination Serial Distribution, para. 11.0, pg. 13.

26.9 Pipe Ridges

Pipe ridges that allow the effluent to flow uninterrupted around the circumference of the pipe (see illustration, para. 2.0, pg. 2).

26.10 Coupling

A plastic fitting that joins two AES pipe pieces in order to form rows (see para.3.4, pg. 3).

26.11 Daily Design Flow

The peak daily flow of wastewater to a system, expressed in gallons per day (GPD); systems are typically sized based on the daily design flow. Design flow calculations are set forth in the State Rules. In general, actual daily use is expected to be one-half to two-thirds less than "daily design flow."

26.12 Differential Venting

A method of venting a system utilizing high and low vents (see para. 20.2, pg. 18).

26.13 Distribution Box or "D-box"

A device designed to divide and distribute effluent from the septic tank equally to each of the outlet pipes that carry effluent into the system. D-boxes are also used for velocity reduction (see para. 18.4, pg. 17).

26.14 D-box Distribution Configuration

A design in which each AES row receives effluent from a distribution box outlet. Such a system is also called a "parallel system" or a "finger system." See D-box Distribution, para. 12.0, pg. 15.

26.15 End-to-End Configuration

Consists of two or more beds constructed in a line (i.e., aligned along the width of the beds).

26.16 Flow Equalizer

An adjustable plastic insert installed in the outlet pipes of a D-box to equalize effluent distribution to each outlet.

26.17 GPD and GPM

An acronym for Gallons per Day and Gallons per Minute respectively.

26.18 H-20

A specification created by the American Association of State Highway Transportation Officials (AASHTO), which describes the maximum axle and wheel loading allowed under this designation. Consult the actual specification for actual loading limits.

26.19 High and Low Vents

Pipes used in differential venting. Detailed information about venting requirements can be found in Venting Requirements, para. 20.0, pg. 18.

26.20 High Strength Effluent

High strength wastewater is septic tank effluent quality that exceeds the requirements of SPS 383.44(2)(a) (see para. 8.7, pg. 9).

26.21 Manifolded Splitter Box

A PVC configuration which connects several distribution box outlets together in order to equalize effluent flow. Refer to drawing, para. 3.7, pg. 3.

26.22 Multiple Bed Distribution

Incorporates two or more beds, each bed with Basic Serial, Combination Serial, or D-box distribution and receiving effluent from a distribution box (see para. 13.0, pg. 15).

26.23 Non-Conventional Configurations

Have irregular shapes or row lengths shorter than 30 ft. to accommodate site constraints (see para. 9.1, pg. 13).

26.24 Offset Adapter

A plastic fitting with a 4 in. hole installed at the 12 o'clock position which allows for connections from one row to another and for installation of venting (see para. 3.2, pg. 3).

26.25 Pressure Distribution

A pressurized, small-diameter pipe system used to deliver effluent to an absorption field. Pressure Distribution is not permitted to be used with the AES system as they are designed to promote even distribution without the need for pressure distribution.

26.26 Pump Systems

Utilize a pump to gain elevation in order to deliver effluent to a D-box (see para. 18.0, pg. 17).

26.27 Raised Connection

A U-shaped, 4" diameter, PVC pipe configuration which is used to connect rows oriented in a serial configuration and to maintain the proper liquid level inside each row. See drawing in para.3.9, pg. 4.

26.28 Raking and Tilling

Refers to methods of preparing the native soil that will be covered with System Sand or sand fill, creating a transitional layer between the sand and the soil. See Installation Requirements para. 22.7, pg. 22.

26.29 Row

Consists of a number of AES pipe sections connected by couplings with an Offset Adapter on the inlet end and an Offset Adapter or End Cap on the opposite end. Rows are typically between 30 ft. and 100 ft. long (see Row Requirements, para. 8.16, pg. 10).

26.30 Sand Fill

Clean sand, free of organic materials and meeting the specifications set forth in Sand Fill, para. 19.2, pg. 18. Sand fill is used to raise the elevation of the system to meet required separation distance or in side slope tapers. System Sand may be used in place of sand fill.

26.31 Section / Serial Section

A group of interconnected rows receiving effluent from one distribution box outlet. Sections are limited to 750 GPD daily design flow maximum.

26.32 Serial Distribution

Two or more AES rows connected by a Raised Connection. Basic Serial distribution is described in detail in para. 9.0, pg. 12. Combination Serial distribution is described in detail in para. 11.0, pg. 13.

26.33 Skimmer Tabs

Projections into the AES pipe that help to capture grease and suspended solids from the existing effluent (see illustration, para. 2.0, pg. 2).

26.34 Side-to-Side Configuration

Consists of two or more beds arranged so that the rows are parallel to one another.

26.35 Slope (3:1)

In this Manual's illustrations, slope is expressed as a ratio of run to rise. Example: A slope with a grade of (3:1) is the difference in horizontal distance of two (3) horizontal ft. (run) over an elevation difference of one (1) ft. (rise).

26.36 Slope (%)

Expressed as a **percent**, is the difference in elevation divided by the difference in horizontal distance between two points on the surface of a landform. Example: A site slope of one (1) percent is the difference in elevation of one (1) ft. (rise) over a horizontal distance of one hundred (100) ft. (run).

26.37 Smearing

The mechanical sealing of soil air spaces along an excavated, tilled or compressed surface. This is also referred to as "compacting." In all installations, it is critical to avoid smearing or compacting the soils under and around the field.

26.38 Surface Diversion

A natural or manmade barrier that changes the course of water flow around an onsite system's soil absorption field.

26.39 System Sand Bed

System Sand area required/used in AES systems. The System Sand bed extends a minimum of 12 in. below, 3 in. above and 6 in. horizontally from the outside edges of the AES pipes.

26.40 System Sand

System Sand must be clean, granular sand free of organic matter and must adhere to the System Sand Specification with no more than 3% passing the #200 sieve (see complete details in para. 3.11, pg. 4).

26.41 System Sand Extension Area

The System Sand extension area is a minimum of 6 in. deep. The System Sand extension is placed on the down slope side of sloping systems. System sloping more than 10% require a 2.5 ft. minimum extension. The System Sand extension is measured from the tall portion of the System Sand bed (see illustration, para. 13.1, pg. 16).

26.42 Topsoil (a.k.a. Loam or Soil Cover Material)

Topsoil, also known as Loam, is soil material cover capable of sustaining plant growth which forms the topmost layer of cover material above the system.

26.43 Velocity Reducer

Velocity reducer refers to any of the various components whose purpose is to reduce the velocity of effluent flow into the AES pipes. A distribution box with a baffle or inlet tee is sufficient for velocity reduction in most systems (see illustration, para. 18.4, pg. 17).
