1.0 Background

Liquid that exits from a septic tank ("effluent") contains suspended solids that can cause traditional systems to fail prematurely. Solids can overload bacteria, cut off air required for aerobic bacterial activity, and/or seal the underlying soil, interfering with its ability to absorb liquid.

1.1 What Our System Does

By utilizing simple yet effective natural processes, the Simple-Septic® (SS) Treatment System treats septic tank effluent in a manner that prevents suspended solids from sealing the underlying soil, increases system aeration, and provides a greater bacterial treatment area ("biomat") than traditional systems.

1.2 Why Our System Excels

The Simple-Septic® Treatment System retains solids in its pipe and provides multiple bacterial surfaces to treat effluent prior to its contact with the soil. The continual cycling of effluent (the rising and falling of liquid inside the pipe) enhances bacterial growth. This all combines to create a unique eco-system that no other passive wastewater treatment system is designed to offer. The result is a system that excels by being more efficient, last longer, and have a minimal environmental impact.

1.3 System Advantages

- a) costs less than traditional systems
- b) eliminates the need for washed stone
- c) often requires a smaller area
- d) installs more easily and quickly than traditional systems
- e) adapts easily to residential and commercial sites of virtually any size
- f) adapts well to difficult sites
- g) develops a protected receiving surface preventing sealing of the underlying soil
- h) blends "septic mounds" into sloping terrain
- i) increases system performance and longevity
- j) tests environmentally safer than traditional systems
- k) recharges groundwater more safely than traditional systems
- l) made from recycled plastic

1.4 Patented Simple-Septic® Technology

The Simple-Septic® (SS) pipes are an onsite wastewater treatment system consisting of a patented configuration of ridged, corrugated, perforated plastic pipe with interior skimmer tabs, surrounded by a geo-textile fabric. The Simple-Septic® pipes are assembled and installed in a bed of specified System Sand which can either be below the ground or above. The system is designed to simultaneously purify and disperse effluent after primary treatment by a septic tank. The system is completely passive, requiring no electricity, motors, alarms, computers, etc.

2.0 Eight Stages of Wastewater Treatment for Simple-Septic® Systems

Stage	Summary of Simple-Septic® System Processes
1	Warm wastewater enters the pipe and is cooled to ground temperature.
2	Suspended solids separate from the cooled liquid wastewater.
3	Skimmer tabs further capture grease and suspended solids from the wastewater as it exits through perforations in the pipe.
4	Pipe ridges allow the wastewater to flow uninterrupted around the circumference of the pipe and aid in cooling.
5	Wastewater passes into the geo-textile fabric and grows a protected bacterial surface.
6	Sand wicks the liquid from the geo-textile fabric and enables air to transfer to the bacterial surface.
7	Fabric provides a large bacterial surface to break down solids.
8	An ample air supply and fluctuating liquid levels increase bacterial efficiency.

3.0 Simple-Septic® Components

3.1 Simple-Septic® Pipe

- a) Plastic pipe made with a significant percentage of recycled material
- b) 10 ft. sections (can be cut to any length)
- c) Ridged and perforated, with skimmer tabs on interior
- d) Wrapped in a non-woven geo-textile fabric stitched in place
- e) Exterior diameter of 12 in.
- f) Each 10 ft. section has a liquid holding capacity of approx. 58 gallons
- g) A 10 ft. length of SS is flexible enough to bend up to 90°

3.2 Offset Adapter and Double Offset Adapter

An offset adapter is a plastic fitting 12 in. in diameter with an inlet hole designed to accept a 4 inch sewer line, raised connection or vent pipe. The hole is to be installed in the 12 o'clock position. The distance from the bottom of the Offset Adapter to the bottom of its inlet hole is 7 in. When assembling pipes into rows, note that the geo-textile fabrics are placed over the edges of the Offset Adapter and Couplings. The Double Offset Adapter has two 4 in. holes. The hole in the 6 o'clock position is designed to accept a bottom drain.

3.3 Coupling

A coupling is a plastic fitting used to create a connection between two pieces of SS pipe. Note that the couplings are wide enough to cover 1 or 2 pipe corrugations on each of the two pipe ends being joined. The couplings feature a snap-lock feature that requires no tools. When assembling pipes into rows, note that the geo-textile fabric does not go under couplings. Pull fabric back, install coupling, and then pull fabric over coupling. Also note that during installation in cold weather, couplings are easier to work with if stored in a heated location (such as a truck cab) before use.

3.4 Raised Connection

A raised connection is a PVC Sewer & Drain pipe configuration which is used to connect SS rows. Raised connections extend 2 in. to 4 in. into pipe and are installed on an angle (as shown below). All PVC joints should be glued.

4.0 Introduction

4.1 Presby Environmental Standards

All SS systems must be designed and installed in compliance with the procedures and specifications described in this Manual and in the product's Massachusetts approval.

4.2 Massachusetts Rules

This Manual is to be used in conjunction with the current State of Massachusetts Department of Environmental Protection Rules, 310 CMR 15.

4.3 Conflicts between Massachusetts Rules & Manual

In the event of contradictions between this Manual and Massachusetts Department of Environmental Protection regulations, Presby Environmental, Inc. should be contacted for technical assistance. Exceptions to any Massachusetts rules other than those specifically discussed in this Manual require a DEP waiver. Please contact us for technical assistance at (800) 473-5298.

4.4 Certification Requirements

Certification classes are required for designers and installers wishing to use Presby Environmental, Inc.'s Simple-Septic® product. Certification is obtained by attending a Certification Course presented by Presby Environmental, Inc. or its sanctioned representative. Certification can also be obtained by viewing tutorial videos on our website (high speed connection required) and then successfully passing a short assessment test, which is also available over the internet. It is recommended that all professionals involved in the inspection, review or certification of SS systems become Presby Certified.

4.5 Technical Support

Presby Environmental, Inc. provides technical support to all individuals using our products. For questions about our products or the information contained in this Manual, or to register for a Certification Course, please contact us at 1-800-473-5298.

5.0 General Design Criteria

5.1 Barrier Materials Over System Sand

No barrier materials (hay, straw, tarps, etc.) are required to be placed between the System Sand and cover material, unless the field is being designed for H-20 loading where stabilization fabric is used (see sect. 5.14, page 5).

5.1 Breakout Elevation

Breakout Elevation is defined as the elevation 6 inches below the Simple-Septic® rows for all percolation rates (see ill. in sect. 6.3, page 8).

5.2 Bottom Drain

A bottom drain is a line connected to the hole in the 6 o'clock position of a double offset adapter at the end of each serial section or each row in a D-Box Distribution Configuration which drains to a sump and is utilized to lower the water level in a saturated system or to facilitate system rejuvenation.

5.3 Center-to-Center Spacing

The required minimum Center-to-Center pipe spacing is 1.5 ft. for 1-61 MPI and 3 ft. for 61-90 MPI.

5.4 Converging Flows Restriction

SS Systems must not be located where surface or ground waters will converge, causing surface water flow to become concentrated or restricted within the soil absorption field (see Site Selection details in sect. 28.0, page 21).

5.5 Daily Design Flow per Bedroom

Bedrooms are calculated at a daily design flow of 110 GPD each. Fields that service more than two residential units should use the commercial loading section of all sizing tables in this manual.

5.6 Daily Design Flow

The **minimum** daily design flow for any single-family residential system on its own lot is two bedrooms (220 GPD) and 300 GPD for any commercial system.

- Certain fixtures, such as jetted tubs, may require an increase in the size of the septic tank.
- Daily design flow for a single bedroom apartment with a kitchen connected to a residence (also sometimes referred to as a “studio” or “in-law apartment”) shall be calculated by adding two additional bedrooms (220 GPD).
- When daily design flow is determined by water meter use for commercial systems, refer to DEP Rules.
- PEI recommends taking the average daily use from a peak month and multiply it by a peaking factor of (2) times minimum.
- Note that “daily design flows” are calculated to assume occasional “peak” usage and a factor of safety; Systems are not expected to receive continuous dosing at full daily design load.

5.7 Distribution Box (D-Box)

A distribution box is a device used to divide effluent flow to more than one portion of a Presby Field. A D-Box is required for all Presby Systems and cannot be used as a substitute for the Inspection Port.

5.8 Distribution Box Manifold

A D-Box manifold is utilized to evenly divide flow to more than one field and is especially useful when designing for large daily design flows. Flow Equalizers are required on all used D-Box outlets.

NOTE: UTILIZING EVERY OTHER OUTLET WILL PROVIDE ROOM FOR REQUIRED PIPING AND ALLOW FOR EASIER INSTALLATION

5.9 Documentation to End User

The Designer must provide the system owner with copies of the State's Certification for General Use and/or Approval for Remedial Use and a "Simple-Septic® Wastewater Treatment Operating Manual." The state approvals are available for download on the Massachusetts DEP website. The Operator's Manual is available for download on our website: www.PresbyEnvironmental.com or call 800-473-5298 to request printed copies.

5.10 End-to-End Beds Preferred Over Side-to-Side Beds

If site conditions permit, End-to-End multiple bed configurations are preferable to Side-to-Side configurations (see sect.9.1, page 10).

5.11 Fill Extensions

Fill extensions are the material used between the Presby System Sand Bed and the beginning of the Side Slope Tapers (see ill. in sect. 6.3, page 8). Fill extensions are constructed on all four sides of a Presby Bed. The Breakout Elevation establishes the elevation at the intersection of the Fill Extension and Side Slope Taper (see ill. in sect. 6.3, page 8).

5.12 Flow Equalizers Required

All distribution boxes used to divide effluent flow require flow equalizers in their outlets. Flow equalizers are limited to a maximum of 20 GPM per equalizer. Flow equalizers are not required when using only one D-Box outlet. Never place a flow equalizer on the outlet leading to a vent.

5.13 Garbage Disposals (a.k.a. Garbage Grinders)

No additional SS pipe is required when using a garbage disposal (grinder). If a garbage disposal is utilized, follow the State's requirements regarding septic tank sizing. Multiple compartment septic tanks or multiple tanks are preferred and should be pumped as needed.

5.14 H-10 AND H-20 Depth of Cover Material

The minimum total depth of cover on SS rows is 10 inches: 6" of system sand plus 4" of topsoil. SS pipe with 12" of structural cover is designed for H-10 loading, and SS pipe with 18" of structural cover and Stabilization Fabric is designed for H-20 loading (the only soil compaction that should take place is at the point of preparation for pavement).

**Enviro-Septic pipe with 18" of structural cover is designed for H-20 loading by Presby Environmental, Inc. The Mass DEP makes no determination that this design meets the H-20 loading requirement.*

5.15 Inspection Ports

At least one Inspection Port is required in each Simple-Septic® field. The Inspection Port is constructed of perforated 4 in. diameter plastic and wrapped with geo-textile fabric to protect against sand infiltration. The bottom of the Inspection Port must extend down to the bottom of the System Sand Bed Bottom, which is 6 in. below the SS pipes for 1-60 MPI and 12 in. for 61-90 MPI. The top of the port should extend to the final grade and use a threaded cap for access. In beds with a less than or equal to 10% System Slope, it must be placed between two of the SS rows; preferably at the end of a serial section. In beds with more than a 10% System Slope, it must be located at the toe of the System Sand Extension (see ill. in sect. 6.3, page 8).

5.16 Row Requirements

- All beds must have at least 2 rows.
- Maximum row length for any system is 100 ft.
- Recommended minimum row length is 30 ft.
- A combination (or D-Box) distribution system must be used if any row length is less than 30 ft. The D-Box must feed at least 30 ft of Presby Pipe (calculated by adding the length of each serial sections first rows), a minimum of two D-Box outlets must be used and the field must be vented. Ex: row length 10 ft requires (3) serial sections (3 rows x 10 ft = 30 ft of pipe directly connected to the D-Box). Illustration of row lengths less than 30 ft:

- e) Row Center-to-Center Spacing is 1.5 ft min. for all systems in 0-60 mpi soils, and 3.0 ft min. in 61-90 mpi soils.
- f) Rows shall be grouped in the middle of the sand bed area when System Sand Extensions are required.
- g) All rows must be laid level to within $\pm 1/2$ in. (total of 1 in.) of the specified elevation and preferably parallel to the contour of the site, although alternate orientations are allowed with proper construction. Contact Technical Support for recommendations.
- h) It is easier if row lengths are designed in exact 10 ft increments since Presby Pipe comes in 10 ft sections. However, if necessary, the pipe is easily cut to any length to meet site constraints.

5.17 Minimum Dispersal Area

To meet Massachusetts' requirements, at no time may a Simple-Septic® system be designed to have a sand bed area less than 40% of a conventional Title 5 aggregate system designed in accordance with 310 CMR 15.00 for the same site.

5.18 Pressure Distribution

- a) The use of pressure distribution with SS Systems is not permitted.
- b) Pump systems to gain elevation are allowed (see Pump System Requirements, sect. 26.0, page 17).

5.19 Row Elevations for Sloping Sites

Elevations must be provided on the construction drawing for each Simple-Septic® row in the sloping bed system.

5.20 Row Orientation

SS rows must be laid level to within $\pm 1/2$ in. of the specified elevation and preferably should be parallel to the contour of the site. The minimum center-to-center spacing is determined by the percolation rate and system slope. The center-to-center spacing may be larger, but not less than the minimum requirement.

5.21 Separation Distances (Vertical and Horizontal)

Vertical and horizontal separation distances are measured from the outermost edge(s) of the System Sand Bed.

The local approving authority may allow the following reductions for remedial use without granting a waiver under 310 CMR 15.400 or obtaining MA DEP approval:

Reduction to Groundwater: The depth to groundwater may be reduced by up to 2 feet, resulting in a minimum separation distance of two feet in soils with a recorded percolation rate of more than two minutes per inch and three feet in soils with a recorded percolation rate of two minutes or less per inch, measured from the bottom of the soil absorption system to the high groundwater elevation; and/or

Reduction of Pervious Material: If a reduction in the depth of the naturally occurring pervious material layer is necessary, a proposed reduction of up to 2 feet may be allowed in the four feet of naturally occurring pervious material layer required by 310 CMR 15.240(1) provided that it has been demonstrated that no greater depth in naturally occurring pervious material can be met anywhere on the site.

5.22 Septic Tank and Distribution Box Elevations (2 in. Rule)

The outlet of a distribution box must be set at least 2 in. above the highest inlet of the SS row, with the connecting pipe slope not less than 1% (approximately 1/8 in. per foot).

5.23 System Installation Form

Installers of Simple-Septic® systems shall provide Presby Environmental, Inc., and the approving authority with a copy of a completed "System Installation Form" for each new or replacement system installed, which can be found at the end of this manual.

5.24 Side Slope Tapers

Side slope tapering is to be no steeper than 3:1; steeper side slope tapering requires a state waiver. The side slope tapers begin 15 feet from the edge of the tall portion of the System Sand bed or 16 ft. when measured from the edge of the SS pipes (see ill. in sect. 6.3, page 8).

5.25 System Sand Requirements for All Beds

It is **critical** to the proper functioning of the SS System that the proper amount and type of System Sand be installed. System Sand is the material in direct contact with all Presby Pipes and must be clean, granular sand free of organic matter and must adhere to ASTM C-33 ("concrete sand") providing that no more than 3% can pass a #200 sieve (verified by washing sample per requirements of ASTM C-117 as noted in the ASTM C-33 specification).

5.26 System Sand Bed Dimension

System Sand dimensions must meet the following minimum requirements:

- 6 in. of System Sand below the SS pipe for (1-60 MPI)
- 12 in. of System Sand below the SS pipe for (61-90 MPI);
- 6 in. of System Sand above the SS pipe (all percolation rates).
- 6 in. of System Sand between all SS rows (1.5 ft. center-to-center row spacing minimum);
- 12 in. of System Sand around the perimeter of the pipes;
- 6 in. deep System Sand Extension (when required). The System Sand Extension is any part of the System Sand bed that is more than 1 ft. away from SS pipes.
- Illustration of System Sand Dimensions:

5.27 System Sand Extension

In systems sloping more than 10%, a System Sand extension is required. The System Sand Extension is any part of the System Sand bed that is more than 1 ft. away from SS pipes and added to the down slope side of the bed. The System Sand extension area is a minimum of 6 in. deep and extends a minimum of 3 ft. beyond the tall portion of the System Sand (4 ft. from the pipe) on the down slope edge of the bed (see ill. of System Sand Extension in sect. 6.3, page 8).

5.28 Surrounding Sand

Surrounding Sand should be either System Sand or Title 5 fill, 310 CMR 15.255 (3). Only Title 5 fill sand or System Sand may be placed under raised systems or where top soil and soil horizons with organic matter have been removed (see Surrounding Sand shown in ill. in sect. 6.3, page 8).

5.29 Ten Foot Increments Work Best

It is easier if row lengths are designed in exact 10 ft. increments since SS pipe comes in 10 ft. sections. However, if necessary, the pipe is easily cut to **any** length to meet site constraints.

5.30 Two Rows Minimum

All beds must have at least 2 rows.

5.31 Topsoil (a.k.a. "Loam")

Suitable earth cover, similar to the naturally occurring soil at the site and capable of sustaining plant growth, is required as the uppermost layer over the entire system (including fill extensions, side slope extensions and System Sand extensions). The topsoil layer should be a minimum of 4 in. deep and should be immediately seeded or mulched in order to prevent erosion.

5.32 Venting Requirements

Venting is required for all Presby Systems (see Venting Requirements, sect. 27.0, page 18). Charcoal filters in vent stacks (for odor control) are not recommended by PEI. They can block air flow and potentially shorten system life. Contact PEI for recommendations in correcting odor problems.

5.33 Velocity Reduction

Reduce the velocity of liquid entering SS pipe to reduce turbulence. A distribution box with a baffle or inlet tee may be adequate for velocity reduction in most systems. When pumping to gain elevation, pump to an oversized distribution box or equivalent with proper baffles or tee at the end of the delivery line (see ill. in sect. 27.4, page 19).

5.34 Wastewater Strength

Where wastewater strength is high, additional SS pipe is recommended. Presby Environmental, Inc. provides free technical support to all individuals using our products. For questions regarding design considerations when treating high strength wastewater, please contact us at: **1-800-473-5298**

5.35 Water Purification Systems

- a) Water purification systems and water softeners should **not** discharge into an SS System. This "backwash" does not require treatment and the additional flow may overload the system.
- b) Consult with your designer and/or installer for alternative means of dispersal.
- c) If there is no alternative means of disposing of this backwash other than in the SS System, then the system will need to be "oversized." Calculate the total amount of backwash in GPD, multiply by 3, and add this amount to the daily design flow when determining the field and septic tank sizing.
- d) Water purification systems and water softeners require regular routine maintenance; consult and follow the manufacturer's maintenance recommendations.

5.35.1 Filters, Alarms & Baffles

- a) Effluent filters are not required for gravity systems. However if used they **must** be properly maintained. Follow manufacturer's instructions regarding required inspections, cleaning and maintenance. Effluent Filters must allow the free passage of air to ensure the proper functioning of the system. A blocked filter in any on-site septic system could interfere with venting, causing the system to convert to an anaerobic state and result in a shortened life.
- b) Massachusetts requires an alarm in all Pumped Systems
- c) All septic tanks must be equipped with baffles to prevent excess solids from entering the SS System and allow air flow up the roof stack.

6.0 Percolation Rates 1-60 MPI Design Considerations

6.1 Design Criteria

In percolation rates 1-60 MPI the following conditions apply:

- a) Presby Systems may be used for both new and remedial system construction.
- b) Reserve area requirements must be in accordance with Massachusetts DEP regulations.
- c) Beds using Basic Serial Distribution may receive up to 500 GPD.
- d) Serial Distribution systems with daily design flows greater than 500 GPD must be designed using Combination or D-Box distribution systems.
- e) Each Serial Section in a Combination system is limited to a daily design flow of 500 GPD.
- f) Parallel Distribution, also known as D-Box configuration, is allowed with all daily design flows.
- g) Non-conventional bed layouts are permitted in these soils.
- h) Tables A, B, C and D control system sizing for this percolation rate range.

6.2 Sloping Sites and Sloping Systems

- a) The percentage of slope in all system drawings refers to the slope of the SS System, not the existing terrain.
- b) Systems that slope greater than 10% require a 3 ft. System Sand Extension on the down slope side of the bed (see ill. in sect. 6.3, page 8)
- c) The system slope and the site slope do not have to be the same.
- d) Maximum site slope is 33% and maximum system slope is 25%.
- e) Center-to-center row spacing is 1.5 ft. minimum.
- f) The slope of the site and/or the system may contain more than one slope provided the maximum allowed slope is not exceeded (see ill. in sect. 9.3, page 11.)

6.3 Fill Extensions and Side Slope Tapers

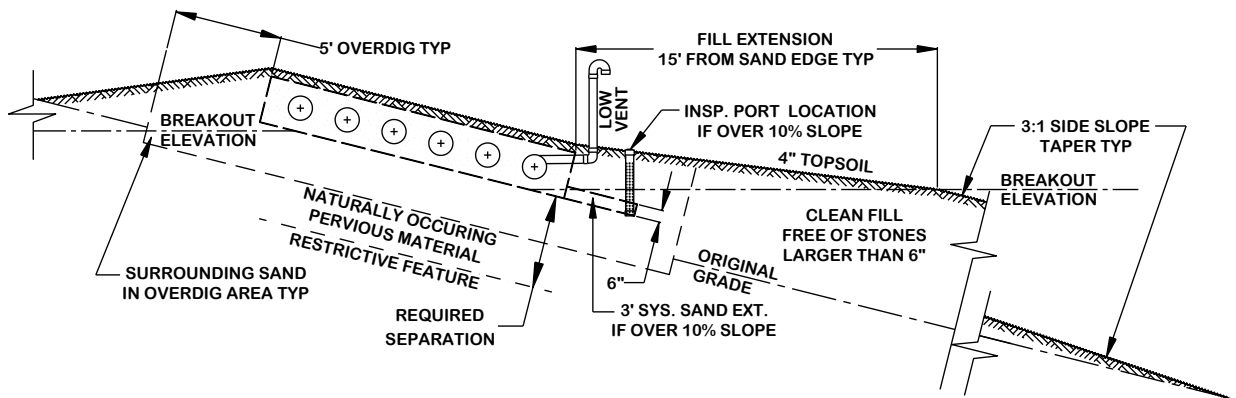

If any portion of the Presby Field extends above the original grade, fill must be used to cover the bed.

- a) A minimum of four inches of topsoil are required over the top of the System Sand Bed.
- b) Fill must extend 15 ft. beyond the edge of the tall portion of the System Sand Bed (do not include the System Sand Extension if present) before the Side Slope Tapers can begin. This applies to all four sides of the field. Use of an impermeable barrier in accordance with DEP rules can reduce this distance to 5 ft. before beginning Side Slope Tapers.
- c) Side Slope Tapers are to be 3 horizontal ft. for each 1 ft. of vertical drop until the fill meets the original grade.
- d) Refer to Installation Requirements in section 29.0, page 21 for proper site preparation, erosion control and surface water diversion procedures.

e) Illustration of a level bed (Raised Connections and D-Box not shown):

f) Illustration of a sloping bed (Raised Connections and D-Box not shown):

7.0 Basic Serial Distribution Layout

Basic Serial distribution may be used for single beds of 500 GPD or less. Basic Serial distribution systems are quick to develop a strong biomat in the first row, provide a longer flow route, improved effluent treatment and ensure air will pass through all the SS rows.

- Basic Serial distribution incorporates rows in serial distribution in a single bed.
- SS rows are connected at the ends with raised connections, using offset adapters and PVC pipe.
- Maximum length of any row is 100 ft.
- Beds must contain a minimum of two rows.
- A Flow Equalizer is not used or required on the single D-Box outlet (flow is not being divided).
- Recommendation: Systems should be designed as long & narrow as the site will allow.
- Basic Serial Distribution Illustration:

8.0 D-Box Distribution

- Distribution box systems are also known as Parallel or Finger systems.
- All rows in this configuration must be the same length.
- Flow equalizers must be used on all used D-Box outlets feeding the field.
- Use a Vent Manifold to connect the ends of all rows to ensure adequate air flow. The manifold is to be sloped toward SS pipes.

- e) Place the D-box on level, firmly compacted soil.
- f) All rows must be laid level end-to-end within $\pm 1/2"$.
- g) D-Box (Parallel) Distribution Illustration for Level Systems:

- h) D-Box (Parallel) Distribution Illustration for Sloping Systems:

9.0 Combination Serial Distribution

Combination Serial distribution within one bed, or multiple beds, is used for systems with daily design flows greater than 500 GPD. Combination Serial distribution is quick to develop a strong biomat in the first row of each section, providing improved effluent treatment. Each Combination Serial section is limited to a maximum loading of 500 gallons/day.

- a) Combination Serial distribution consists of two or more serial sections installed in a single bed.
- b) Each Serial Section consists of a series of SS rows connected at the ends with raised connections, using offset adapters and 4 in. diameter PVC sewer and drain pipe (up to schedule 40 may be used).
- c) Each serial section has a maximum daily design flow of 500 GPD. Ex: Daily design flow = 1,000 GPD requires $(1,000 \div 500) = 2$ sections min. More than the minimum number of sections may be used.
- d) Each section must have the same minimum linear feet of pipe. The minimum linear feet of pipe per section is determined by dividing the total linear feet required in the SS system by the number of sections required. A section may exceed the minimum linear length. Rows within a section may vary in length to accommodate site constraints. There is no limit on the number of Serial Sections within a Combination bed.
- e) Combination Serial System Illustration:

Note: When the vent manifold is on the same side as the serial section inlets, the manifold runs over the top of these inlets (as shown).

9.1 Multiple Bed Distribution

Multiple Bed distribution incorporates two or more beds, each bed with Basic Serial, Combination Serial, or D-Box distribution, and each receiving an equal amount of effluent from a D-Box. Multiple beds may be oriented along the contour of the site or along the slope of the site. End-to-end configurations are preferred to side-to-side configurations (comply with bed separation distance per Massachusetts rules).

End-to-End Illustration:

Side -to-Side Illustration:

9.2 Butterfly Configuration

A Butterfly Configuration system is considered a single bed system and may be constructed with Basic Serial, D-Box or Combination distribution. Illustration of a Butterfly configuration:

9.3 Multiple Slope Beds

For multiple slope beds, if any portion of the bed has a system slope greater than 10%, a system sand extension is required. Beds with multiple slopes (Inspection Port not shown):

10.0 In-Ground Bed Systems

SS Systems are installed below existing grade for sites with no soil restrictive features to limit placement. In-Ground systems are limited to percolation rates of 1-60 MPI. In-Ground systems may be constructed as either level or sloping beds.

11.0 Elevated Bed Systems (Mounds)

Elevated SS Systems are designed for sites with soil, depth to groundwater or restrictive feature constraints that do not allow for In-Ground Bed Systems. An Elevated bed system is a soil absorption field with any part of the SS system above the original grade. Elevated beds may be constructed as either level or sloping beds (see ill. in sect. 6.3, page 8).

12.0 Non-Conventional System Configurations (1-60 MPI)

Non-conventional system configurations may have irregular shapes to accommodate site constraints. A site specific waiver from the state may be required for non-conventional configurations.

- Non-Conventional Configurations are limited to percolation rates 1-60 MPI.
- Maximum row length is 100 ft.
- Each section or bed must have at least the minimum linear feet of pipe (total feet of pipe required divided by number of sections equals the minimum number of feet required for each section or bed).
- Rows within a section or bed may vary in length to accommodate site constraints except when using a D-Box configuration.

12.1 Curves

Curved configurations work well around structures, setbacks, and slopes. Multiple curves can be used within a system to accommodate various contours of the site.

12.2 Non-Conventional Basic Serial and Combination Serial Configuration

13.0 Table A: Simple-Septic® Pipe Required (1 – 60 MPI)

The SS pipe required is calculated at 50 ft. per bedroom for residential systems and 50 ft. of pipe per 100 GPD of daily flow for commercial systems (see sect. 5.34 on page 7 for high strength wastewater).

Table A: Minimum SS Pipe Requirements (1-60 MPI)

Perc. Rate (MPI)	Bedrooms						*Commercial per 100 GPD
	2	3	4	5	6	Additional Room	
1-60	100	150	200	250	300	50	50

SS Pipe Required min. (ft.)

* Minimum commercial daily flow is 300 GPD

14.0 Table B: Long Term Acceptance Rate (LTAR)

Find the percolation rate and soil class to determine the LTAR (Long Term Acceptance Rate) in GPD/sq. ft. The 40% reduction in bed area allowed by DEP is already reflected in the values.

Table B: Long Term Acceptance Rate (1-60 MPI)

Perc. Rate (MPI)	Soil Class I	Soil Class II	Soil Class III	Soil Class IV
≤ 5	1.233	1.000		
6	1.166	1.000		
7	1.133	1.000		
8	1.100	1.000		
10		1.000		
15		0.933	0.616	
20		0.883	0.566	
25		0.666	0.550	
30		0.550	0.483	
40			0.416	
50			0.333	0.333
60			0.250	0.250

LTAR Maximum (GPD/sq. ft.)

When percolation rate is between those listed in Table B, the next slower rate shall be used for design purposes.

15.0 Table C: System Sand Bed Area

Use Table C below to determine the appropriate minimum System Sand dispersal area. Note: minimum daily design flow for commercial systems is 300 GPD and minimum System Sand bed area is 400 sq. ft. The 40% reduction in bed area allowed by DEP is already reflected in the values.

Table C: System Sand Bed Area Required Minimum (1 – 60 MPI)

LTAR (GPD/sq.ft.)	Number of Bedrooms					Additional Bedroom (110 GPD)	*Commercial Per 100 GPD
	2 Bedrooms (220 GPD)	3 Bedrooms (330 GPD)	4 Bedroom (440 GPD)	5 Bedroom (550 GPD)	6 Bedroom (660 GPD)		
1.233	400	400	400	447	536	90	82
1.166	400	400	400	472	567	95	86
1.133	400	400	400	486	583	98	89
1.100	400	400	400	500	600	100	91
1.000	400	400	440	550	660	110	100
0.933	400	400	472	590	708	118	108
0.883	400	400	499	623	748	125	114
0.666	400	496	661	826	991	166	151
0.616	400	536	715	893	1,072	179	163
0.566	400	584	778	972	1,167	195	177
0.550	400	600	800	1,000	1,200	200	182
0.483	456	684	911	1,139	1,367	228	208
0.416	529	794	1,058	1,323	1,587	265	241
0.333	661	991	1,322	1,652	1,982	331	301
0.250	880	1,320	1,760	2,200	2,640	440	400
System Sand Bed Area Minimum (sq.ft.)							

16.0 Table D: Number of Rows and Pipe Layout Width

Table D: Number of Rows and Pipe Layout Width (1-60 mpi)

Length ft.	Total Linear Feet of Enviro-Septic®													
20	40	60	80	100	120	140	160	180	200	220	240	260	280	300

Spacing														
1.50	2.50	4.00	5.50	7.00	8.50	10.00	11.50	13.00	14.50	16.00	17.50	19.00	20.50	22.00
	Pipe Layout Width ft. (outermost edges of rows)													

To use Table D: select a row length and move right until the minimum amount of pipe is found (more is allowed). Then move down to find the number of rows required. Continue downward in the same column until adjacent to the row spacing and find the pipe layout width. Example (highlighted above): 200 ft. of pipe required, using row length of 40 and 1.50 ft. spacing will require (5) rows resulting in a pipe layout width of 7.00 ft. Note: Pipe layout width is always (2) ft. less than the System Sand Bed width.

17.0 Design Procedure (1 – 60 MPI)

Task #1: Find the minimum amount of SS required from **Table A** using the daily design flow. See paragraph 9.0 on page 10 for daily flows over 500 GPD to determine the minimum number of serial sections required.

Task #2: Find the LTAR from **Table B** using the soil's percolation rate and soil class.

Task #3: Using the LTAR from Task 2, find the minimum System Sand bed area from **Table C**.

Task #4: Select a row length and calculate the number of rows required. Also determine the pipe layout width using **Table D**.

Task #5: Calculate the System Sand Bed dimensions and confirm the area meets **Table C** requirement. Note: if the system slope is over 10% and additional 3 ft. system sand extension is required on the downslope side of the bed. The system sand extension may be counted in the sand bed area requirement from Table C.

Design Example 1: 3 bedrooms, a percolation rate of 13 MPI in Class II soils, 1.5 ft. row spacing, and level site:

Task #1: from **Table A** using a daily flow of 3 bedrooms (330 GPD) requires 150 ft. of SS pipe minimum.

Task #2: from **Table B** and a 13 MPI percolation rate on class II soils requires a maximum LTAR of 0.933 GPD/sq.ft.

Task #3: from **Table C** using an LTAR of 0.933 and daily design flow of 3 bedrooms requires a minimum of 400 sq. ft. of System Sand bed area.

Task #4: from **Table D** using a row length of 50 ft. and a row spacing of 1.5 ft., 3 rows are required resulting in a pipe layout width of 4 ft.

Task #5: Final System Sand Bed dimensions - System Sand bed length = 50 ft. + 2 ft. = 52 ft.

- System Sand bed width = 4 ft. + 2 ft. = 6 ft. min. to accommodate all pipes. System Sand Bed Area for this design = 6 ft. x 52 ft. = 312 sq. ft. which is less than the 400 sq. ft. required. Because the system is level, no system sand extension is required, so to find the minimum sand bed width divide 400 by 52 = 7.7 ft. Our final sand bed area is 8 ft. x 52 ft. = 416 sq. ft.

Illustration of Design Example #1 (Basic Serial System):

Design Example 2: 5 bedrooms, a percolation rate of 8 MPI in Class I soils, 1.5 ft. row spacing on 11% site:

Task #1: from **Table A** using a daily flow of 5 bedrooms (550 GPD) requires 250 ft. of SS pipe minimum and (2) serial sections (550÷500=1.1, rounded up to two sections minimum).

Task #2: from **Table B** using an 8 MPI percolation rate on class I soils requires a max. LTAR of 1.100 GPD/sq.ft.

Task #3: from **Table C** using an LTAR of 1.100 and daily design flow of 5 bedrooms requires a minimum of 500 sq. ft. of System Sand bed area.

Task #4: from **Table D** using a row length of 62.5 ft. and a row spacing of 1.5 ft., 4 rows are required resulting in a pipe layout width of 5.5 ft.

Task #5: Final System Sand Bed dimensions:

System Sand bed length = 62.5 ft. + 2 ft. = 64.5 ft.

System Sand bed width = 5.5 ft. + 2 ft. + 3 ft. System Sand extension (slope over 10%) = 10.5 ft.

System Sand Bed Area for this design = 64.5 ft. x 10.5 ft. = 677.25 sq. ft. which is greater than the 500 sq. ft. required. No adjustment to the row spacing is required.

Illustration of Design Example #2 (Combination System):

18.0 Design & Sizing Criteria for Percolation Rates (61–90 MPI)

All systems in this percolation rate range must be:

- Restricted to Remedial Use only and have a full size reserve area per DEP rules.
- Designed with the bottom of System Sand Bed at or above the original grade.
- 500 GPD maximum per bed.
- Vertical offset to restrictive features is measured from 6 in. below the SS pipe.
- Must use Basic Serial Distribution (limited to 500 GPD per bed).
- Level bed center-to-center row spacing 3 ft. min. with rows grouped in center of sand bed.
- Sloping bed center-to-center row spacing 1.5 ft. with rows grouped at high side of sand bed.
- 12" of System Sand is required below all Simple-Septic® pipes.
- Non-Conventional Configurations may not be used.

19.0 Simple-Septic® Pipe Requirement (61-90 MPI)

Simple-Septic pipe requirement is calculated at 80 ft. per bedroom for residential systems and 85 ft. per 100 GPD for commercial systems. For high strength effluent contact Technical Support (800-473-5298).

20.0 Table E: Allowable System Slope (61-90 MPI)

Perc. Rate Range (MPI)	System Slope Max. (%)
61-70	15
71-80	10
81-90	5

21.0 Table F: System Sand Bed Area (61-90 MPI)

Daily Design Flow	*System Sand Bed Area Min. (sq.ft.)
2 Bedrooms	880
3 Bedrooms	1,320
4 Bedrooms	1,760
Each Additional Bedroom	440
Commercial per 100 GPD	400

* Table F: System Sand Bed Area noted is based on a 40% reduction in dispersal area when calculated using a 0.15 GPD/sq.ft. loading rate. No further reduction is allowed.

22.0 Table G: Row Length Minimum (61-90 MPI)

Perc. Rate Range (MPI)	Bedrooms				Commercial per 100 GPD
	2	3	4	Each Add'l	
61-70	60	70	80	10	40
71-80	70	80	90	10	40
81-90	80	90	100	10	40

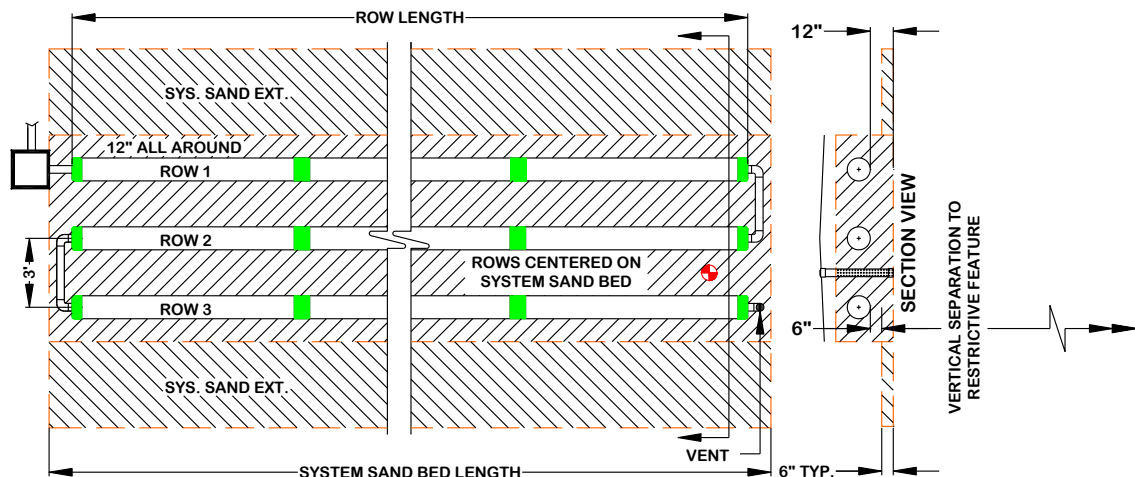

Row Length Min. (ft.)

Use this table to determine minimum Presby Pipe Row length.

23.0 Centered Rows - Level Systems (61-90 MPI)

Level beds for 61-90 MPI require 3 ft. min. center to center row spacing and are grouped in the middle of the bed.

Plan View:

Section View on next page.

Section View:

24.0 Grouped Rows - Sloping Systems (61-90 MPI)

Sloping beds for 61-90 MPI have 1.5 ft. min. row spacing and are grouped at the high side of the bed. The inspection port is placed at the end of system sand extension.

Plan View:

Section View:

25.0 Design Procedure (61 – 90 MPI)

Task 1: Find the minimum amount of SS pipe required using the daily design flow (80 ft./bedroom).

Task 2: Center-to-center row spacing is 3 ft.

Task 3: Verify allowable system slope from **Table E** (if planning to slope bed).

Task 4: Find the minimum System Sand Bed Area from **Table F** using the daily design flow.

Task 5: Select a row length suitable for the site that meets the minimum row length requirement from **Table G** and then calculate the number of rows required.

Task 6: Calculate the System Sand Bed Width and confirm it meets **Table E** requirement. Increase the system sand bed width as necessary. Row spacing may also be increased.

25.1 Design Example - Single Family Residence

Design Criteria: three bedrooms (330 GPD), 80 MPI percolation rate, and construct the bed level

Task 1: SS pipe required for (3) bedrooms = $3 \times 80 \text{ ft./bedroom} = 240 \text{ ft. min.}$

Task 2: Center-to-center row spacing is 3 ft.

Task 3: Level beds allowed for all percolation rates.

Task 4: Table F requires 1,320 sq. ft. of System Sand Bed Area minimum.

Task 5: The site will accommodate the 80 ft. minimum row length specified by Table G. This will result in a bed with (3) rows, which provides the minimum 240 ft. required by Task 1.

Task 6: The System Sand Bed Length is the 80 ft. row length + 2 ft. = 82 ft. Now we can calculate the minimum System Sand Bed Width = $1,320 \text{ sq. ft.} \div 82 = 16.1 \text{ ft.}$

System Illustration:

26.0 Pumped System Requirements

Pumped systems supply effluent to the SS System using a pump and distribution box when site conditions do not allow for a gravity system. Dosing siphons are also an acceptable means of delivering effluent to the system.

26.1.1 Alarm

Massachusetts requires alarms for all pump systems.

26.1.2 Differential Venting

All pump systems and dosing siphons must use differential venting (see Differential Venting, sect. 27.2, page 18).

26.1.3 Distribution Box Manifold

If a distribution box manifold is utilized, velocity reduction of the incoming effluent is necessary (see Velocity Reduction, sect. 26.1.4, page 17 and Ill. of Manifolded D-Box in sect. 5.7, page 4).

26.1.4 Velocity Reduction

The rate at which effluent enters the SS must be controlled. Excessive effluent velocity can disrupt solids that settle in the pipes.

- Effluent must never be pumped directly into SS pipe.
- A distribution box or tank must be installed between the pumping chamber and the SS pipe to reduce effluent velocity.
- Force mains must discharge into a distribution box (or equivalent) with velocity reducer and a baffle, 90° bend, tee or equivalent (see ill. in sect. 27.4, page 19).

26.1.5 Dose Volume

- a) Pump volume per dose must be no greater than 1 gallon times the total linear feet of SS pipe.
- b) Pump dosing should be designed for a minimum of 6 cycles per day.
- c) If possible, the dosing cycle should provide at least one hour of drying time between doses.

26.1.6 Basic Serial Distribution Limit

Pumped systems with Basic Serial distribution are limited to a maximum dose rate of 40 gallons per minute. The D-Box outlet does not need a flow equalizer (no effluent is being divided). Never pump directly into SS pipe.

26.1.7 Combination and Multiple-Bed Distribution Limit

All SS Systems with Combination Serial distribution or Multiple Bed distribution must use flow equalizers in each distribution box outlet. Each Bed or section of Combination Serial distribution is limited to a maximum of 20 gallons per minute, due to the flow constraints of equalizers. Example: pumping to a combination system with 3 sections (using 3 d-box outlets). The maximum delivery rate is $(3 \times 20) = 60$ GPM. Always provide a means of velocity reduction.

27.0 Venting Requirements

27.1 General Rules

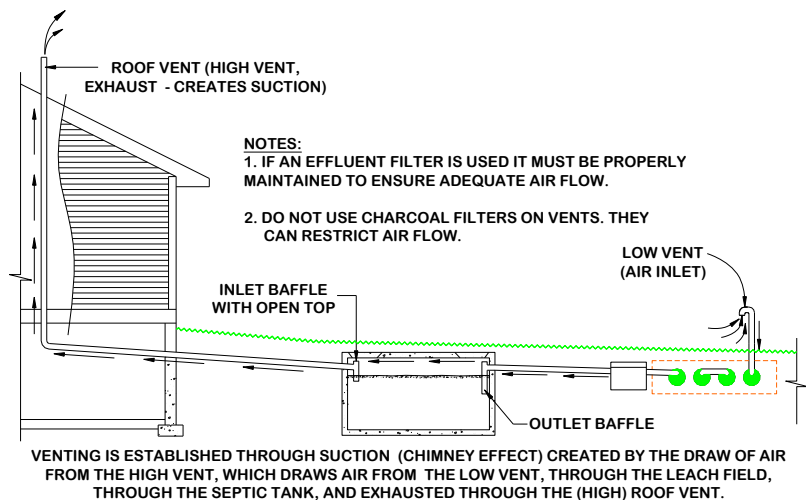

- a) Adequate air supply is essential to the proper functioning of the SS System.
- b) Venting as described below is required for all systems.
- c) Vent openings must be located to ensure the unobstructed flow of air through the entire SS System.
- d) The low vent inlet must be a minimum of 3 ft. above final grade.
- e) One 4 in. vent is required for every 1,000 feet of SS pipe.
- f) A single 6 in. vent may be installed in place of up to three 4 in. vents.
- g) If a vent manifold is used, it must be at least the same diameter as the vent(s).
- h) When venting multiple beds, it is preferred that each bed be vented separately rather than manifolding bed vents together.
- i) Remote Venting (see, sect. 27.8, page 20) may be utilized to minimize the visibility of vent stacks.

27.2 Differential Venting

- a) Differential venting is the use of high and low vents in a system.
- b) In a gravity system, the roof stack acts as the high vent.
- c) High and low vent openings must be separated by a minimum of 10 vertical feet.
- d) If possible, the high and low vents should be of the same capacity.
- e) Sch. 40 PVC or equivalent should be used for all vent stacks.

27.3 Vent Locations for Gravity Systems

- a) A low vent through an offset adapter is installed at the end of the last row of each section or the end of the last row in a Basic Serial bed, or at the end of each row in a D-Box Distribution Configuration system. A vent manifold may be used to connect the ends of multiple sections or rows.
- b) The house (roof) vent functions as the high vent as long as there are no restrictions or other vents between the low vent and the house (roof) vent.
- c) When the house (roof) vent functions as the high vent, there must be a minimum of a 10 ft. vertical differential between the low and high (roof) vent openings.

27.4 Pump System Vent Locations

- A low vent is installed through an offset adapter at the end of each section, Basic Serial bed or attached to a vent manifold.
- A high vent is installed through an unused distribution box outlet (see diagram at right). See Section 27.9 for Bypass Venting details.
- A 10 ft. minimum vertical differential is required between high and low vent openings.
- When venting multiple beds, it is preferred that each bed be vented separately (have their own high and low vents) rather than manifolding bed vents together.
- The low vent may be attached to the D-box and the high vent attached to the end of the last row (or manifold) only when the D-box is insulated against freezing.
- Illustration of Differential Venting for Pump Systems:

27.5 Vent Manifolds

A vent manifold may be incorporated to connect the ends of a number of sections or rows of SS pipe to a single vent opening. Vent Manifold in a Combination System:

27.6 Venting D-Box Configuration

D-box Configurations require the ends of all rows be manifolded together. The vent stack must be attached to the manifolded rows.

27.7 Vent Piping Slope

Vent piping should slope downward toward the system to prevent moisture from collecting in the pipe and blocking the passage of air.

If site conditions do not allow the vent pipe to slope toward the system, or the owner chooses to utilize remote venting for aesthetic reasons (causing the vent pipe not to slope toward the system), the low point of the vent line must be drilled creating several ¼ in. holes to allow drainage of condensation. This procedure may only be used if the vent pipe connecting to the system has a high point that is above the highest point of all SS pipes or the D-Box.,

Venting:

28.0 Site Selection

28.1 Determining Site Suitability

Refer to Massachusetts Rules regarding site suitability requirements.

28.2 Topography

The system must be located in an area that does not concentrate water, both surface and subsurface. If allowed by state and local authorities, altering the terrain upslope of a system may alleviate this requirement if the waters are sufficiently altered to redirect flows away from the field. Avoid swales, low areas, or toe-of-slope areas that may not provide sufficient drainage away from the system.

28.3 Surface Water Diversions

Surface water runoff must be diverted away from the system. Diversions must be provided up-slope of the system and designed to avoid ponding. Systems must not be located in areas where surface or groundwater flows are concentrated.

28.4 Dispersal Area

Systems must be located where adjacent soils in the proposed system location and a 50 ft. perimeter are suitable for dispersing water away from the system.

28.5 Containment

Systems should not be located where structures such as curbs, walls or foundations might adversely restrict the soil's ability to transport water away from the system.

28.6 Hydraulic loading

Systems should not be located where lawn irrigation, roof drains, or natural flows increase water loading to the soils around the system.

28.7 Access

Systems should be located to allow access for septic tank maintenance and to at least one end of all SS rows whenever possible. Planning for future access will facilitate Rejuvenation in the unlikely event the system malfunctions. (See System Bacteria Rejuvenation and System Expansion, sect. 30.0, page 23.)

28.8 Rocky or Wooded Areas

Avoid locating systems in rocky or wooded areas that require additional site work, since this may alter the soil's ability to accept water. No trees or shrubs should be located within 10 ft. of the system to prevent root infiltration.

29.0 Installation Requirements, Component Handling and Site Preparation

29.1 Component Handling

- a) Keep mud, grease, oil, etc. away from all components.
- b) Avoid dragging pipe through wet or muddy areas.
- c) Store pipe on high and dry areas to prevent surface water and soil from entering the pipes or contaminating the fabric prior to installation.
- d) The outer fabric of the SS pipe is ultra-violet stabilized; however, this protection breaks down after a period of time in direct sunlight. To prevent damage to the fabric, cover the pipe with an opaque tarp if stored outdoors.

29.2 Critical Reminder Prevent Soil Compaction

It is critical to keep excavators, backhoes, and other equipment off the excavated or tilled surface of a bed. Before installing the System Sand, excavation equipment should be operated around the bed perimeter; not on the bed itself.

29.3 Site Preparation Prior to Excavation

- a) Locate and stake out the System Sand bed, extension areas and soil material cover extensions on the site according to the approved plan.
- b) Install sediment/erosion control barriers prior to beginning excavation to protect the system from surface water flows during construction.
- c) Do not travel across or locate excavation equipment within the portion of the site receiving System Sand.
- d) Do not stockpile materials or equipment within the portion of the site receiving System Sand.
- e) It is especially important to avoid using construction equipment down slope of the system to prevent soil compaction.

29.4 When to Excavate

- Where wet soils are encountered, follow the DEP requirements from 310 CMR 15.255(6) to maintain soil integrity.
- Do not excavate the system area immediately before, during, or after precipitation.

29.5 Tree Stumps

- Tree stumps shall be removed from the receiving area.
- Avoid soil disturbance, relocation, or compaction.
- Avoid mechanical leveling or tamping of dislodged soil.
- Fill all voids created by stump or root removal with System Sand.

29.6 Raking and Tilling Procedures

All areas receiving System Sand, sand fill and fill extensions **must** be raked or tilled. If a backhoe/excavator is used to till the site, fit it with chisel teeth and till the site. The excavator should remain outside of the proposed System Sand area and extensions. Equipment with tires must never enter the receiving area due to likely wheel compaction of underlying soil structures.

- For **in-ground bed systems**, excavate the system bed as necessary below original grade. Using an excavator or backhoe, tilt the bucket teeth perpendicular to the bed and use the teeth to rake furrows 2 in.- 6 in. deep into the bottom of the entire area receiving System Sand or sand fill ("receiving area").
- For **elevated bed systems** remove the "O" horizon (all organics) "A" topsoil (1-60 MPI only) and "E" mineral layers, then use an excavator or backhoe to rake furrows 7 in. – 8 in. deep (12 in. deep for 61-90 MPI) into the receiving area. Create a transition layer by tilling System Sand or sand fill into the receiving layer prior to bed construction.

29.7 Organic Material Removal

Before tilling, remove all grass, leaves, sticks, brush and other organic matter. For 1-60 MPI systems also remove the "A" topsoil and "E" mineral layers from the excavated system site. For 61-90 MPI systems remove all organics but leave the topsoil in place. It is not necessary for the soil of the system site to be smooth when the site is prepared.

29.8 Install System Sand and/or Sand Fill Immediately After Excavation

- To protect the tilled area (System Sand bed area and System Sand extension area) from damage by precipitation, System Sand should be installed immediately after tilling (6 in. minimum).
- When installing the System Sand, work off either end or the uphill side of the system to avoid compacting soil (see "Critical Reminder" in sect. 29.2, page 21).
- When installing System Sand, keep at least 6 in. of sand between the vehicle tracks and the tilled soil of the site if equipment must work on receiving soil.
- Track construction equipment should not travel over the installed system area until at least 12 in. of cover material is placed over the SS pipes.
- Heavy equipment with tires must never enter the receiving area due to likely wheel compaction of underlying soil structures.

29.9 Distribution Box Installation

To prevent movement, be sure D-boxes are placed level on compacted soil, sand, pea gravel base, or concrete pad.

29.10 Level Row Tolerances

Use a laser level or transit to install rows level. Variations beyond a total of 1 in. ($\pm 1/2$ " from specified elevation) may affect system performance and are not acceptable.

29.11 Row Spacers

System Sand may be used to keep pipe in place while covering, but simple tools may also be constructed for this purpose. Two examples are shown to the right. One is made from rebar, the other from wood. Center-to-center row spacing noted in this manual are minimum distances. Larger row spacing is

always allowed. Caution: Remove all tools used as row spacers before final covering.

29.12 Connect Rows Using Raised Connections

Raised connections consist of offset adapters, 4 in. PVC sewer and drain pipe (the Offset Adapter will accept up to 4 in. sch. 40 PVC), and 90° elbows. Use raised connections to connect the rows of the SS System (see sect. 3.4, p. 3).

29.13 Backfilling Rows

- a) Spread System Sand between the rows.
- b) Stand between two rows of pipe and walk heel-to-toe its entire length, ensuring that System Sand fills all void spaces beneath the SS pipe. Repeat this for all the rows.
- c) Finish spreading System Sand to the top of the rows and leave them exposed for inspection purposes.

29.14 Backfilling and Final Grading

Spread System Sand to a minimum of 6 in. over the pipe and a minimum of 12 in. beyond the SS rows on all four sides. Spread soil material free of organics, stones over 4 in. and building debris, having a texture similar to the soil at the site, without causing compaction. Construction equipment should not travel over the installed system area until at least 12 in. of cover material is placed over the SS pipes (H-10 Loading). 18 in. of cover material over the SS System is required for H-20 loading (see sect. 5.14, page 5).

29.15 Fill Extensions Requirements

All SS Systems with any portion of the System Sand bed above original grade require fill extensions on all sides beyond the outside edge of all pipes starting at the edge of the System Sand then tapering to meet existing grade at a maximum slope of 3:1. In a system sloping more than 10%, a 3 ft. System Sand extension is required on the down slope edge of the bed. See Fill Extensions and Side Slope Tapers, sect. 6.3, page 8.

29.16 System Soil Cover Material

A minimum of 4 in. of suitable earth cover (topsoil or loam), with a texture similar to the soil at the site and capable of sustaining plant growth, must be placed above the installed system. Refer to Topsoil ("a.k.a" Loam), sect. 5.31, page 7.

29.17 Erosion Control

To prevent erosion, soil cover above the system shall be planted with native, shallow-rooted vegetation such as grass, wildflowers and certain perennials or ground covers.

30.0 System Bacteria Rejuvenation and Expansion

This section covers procedures for bacteria rejuvenation and explains how to expand existing systems.

Note: Presby Environmental, Inc. must be contacted for technical assistance prior to attempting rejuvenation procedures.

30.1 Why would System Bacteria Rejuvenation be Needed?

Bacteria rejuvenation is the return of bacteria to an aerobic state. Flooding, improper venting, alteration or improper depth of soil material cover, use of incorrect sand, sudden use changes, introduction of chemicals or medicines, and a variety of other conditions can contribute to converting bacteria in any system from an aerobic to an anaerobic state. This conversion severely limits the bacteria's ability to effectively treat effluent, as well as limiting liquids from passing through. A unique feature of the SS System is its ability to be rejuvenated in place.

30.2 How to Rejuvenate Bacteria

System bacteria are "rejuvenated" when they return to an aerobic state. By using the following procedure, this can be accomplished in most SS Systems without costly removal and replacement. Notification of the local Health Officer may be required before attempting any rejuvenation.

1. Contact Presby Environmental before attempting Rejuvenation for technical assistance.
2. Determine the problem causing the bacteria conversion.
3. Drain the system by excavating one end of all the rows and removing the offset adapters.
4. If foreign matter has entered the system, flush the pipes.
5. Safeguard the open excavation.
6. Guarantee a passage of air through the system.
7. Allow all rows to dry for 72 hours minimum. The System Sand should return to its natural color.
8. Re-assemble the system to its original design configuration. As long as there is no physical damage to the SS components, the original components may be reused.

30.3 System Expansion

SS Systems are easily expanded by adding equal lengths of pipe to each row of the original design or by adding additional equal sections. All system expansions must comply with State and local regulations. Permits may be required prior to system expansion.

30.4 Reusable Components

SS components are not biodegradable and may be reused. In cases of improper installation it may be possible to excavate, clean, and reinstall all system components.

30.5 System Replacement

If an SS System requires replacement:

- a) Remove the existing components and contaminated sand.
- b) Replace in the same excavated location with new System Sand.
- c) If components are not damaged, they may be flushed and reused.
- d) All system replacements must comply with State and Local regulations.

31.0 Operation & Maintenance

31.1 Proper Use

The SS Wastewater Treatment System requires minimal maintenance provided the system is not subjected to abuse. An awareness of proper use and routine maintenance will guarantee system longevity. We encourage all system owners and service providers to obtain and review a copy of our Owner's Manual, available from our website www.PresbyEnvironmental.com or via mail upon request to (800) 473-5298 or info@presbyeco.com.

31.2 System Abuse Conditions

The following conditions constitute system abuse:

- a) Liquid in high volume (excessive number of occupants, excessive use of water in a short period of time, leaking fixtures, whirlpool tubs, hot tubs, water softening equipment or additional water discharging fixtures if not specified in system design).
- b) Solids in high volume (excessive number of occupants, paper products, personal hygiene products, garbage disposals or water softening equipment if not specified in system design)
- c) Antibiotic medicines in high concentrations
- d) Cleaning products in high concentrations
- e) Fertilizers or other caustic chemicals in any amount
- f) Petroleum products in any amount
- g) Latex and oil paints
- h) System suffocation (compacted soils, barrier materials, etc.)

Special Note: Presby Environmental, Inc., and most regulatory agencies do not recommend the use of septic system additives.

31.3 System Maintenance/Pumping of the Septic Tank

- a) Inspect the septic tank at least once every two years under normal usage.
- b) Pump the tank when surface scum and bottom sludge occupy one-fourth or more of the liquid depth of the tank.
- c) If a garbage disposal is used, the septic tank will likely require more frequent pumping.
- d) After pumping, inspect the septic tank for integrity to ensure that no groundwater is entering it. Also check the integrity of the tank inlet and outlet baffles and repair if needed.
- e) Inspect the system to ensure that vents are in place and free of obstructions.
- f) Effluent filters (if used) require ongoing maintenance due to their tendency to clog and cut off oxygen to the System. Follow filter manufacturer's maintenance instructions and inspect filters frequently.

31.4 Site Maintenance

It is important that the system site remain free of shrubs, trees, and other woody vegetation to within a minimum of 10 ft. of the system, including the entire System Sand bed area, and areas impacted by side slope tapering and perimeter drains (if used). Roots can infiltrate and cause damage or clogging of system components. If a perimeter drain is used, it is important to make sure that the outfall pipes are screened to prevent animal activity. Also check outfall pipes regularly to ensure that they are not obstructed in any way.

32.0 Glossary

This Manual contains terminology which is common to the industry and terms that are unique to the Simple-Septic® Systems. While alternative definitions may exist, this section defines how these terms are used in this Manual.

32.1 Simple-Septic® (SS) Pipe

A single unit comprised of corrugated plastic pipe which is surrounded by a sewn geo-textile fabric, is 10 ft. in length, with an outside diameter of 12 in. and a storage capacity of approximately 58 gallons. Each foot of Simple-Septic® provides over 15 sq.ft. of total surface area for bacterial activity. The sewn seam is always oriented up (12 o'clock position) within the bed. Pipes are joined together with couplings to form rows. Simple-Septic® is a combined wastewater treatment and dispersal system. (See definition of Row below.)

32.2 Simple-Septic® Systems

An onsite wastewater treatment and dispersal system constructed using SS pipe in a System Sand bed that receives septic tank effluent through Basic Serial distribution, Combination Serial distribution, Distribution Box ("parallel") or Multiple Bed distribution.

32.3 Basic Serial Distribution

Basic Serial distribution incorporates SS rows in serial distribution in a single bed. See Basic Serial Distribution in sect. 7.0, on page 9.

32.4 Bottom Drain

A Bottom Drain is a line connected to the hole in the 6 o'clock position of a Double Offset Adapter at the end of each serial section or each row in a D-Box Distribution Configuration which drains to a sump and is utilized to lower the water level in a saturated system or to facilitate system rejuvenation.

32.5 Butterfly Configuration

A variation of a standard, single bed system with the D-box located in the center, with rows oriented symmetrically on either side, and with each side or section receiving an equal volume of flow from the D-Box. See Butterfly Configuration, sect. 9.2, on page 11.

32.6 Center-to-Center Row Spacing

The distance from the center of one SS row to the center of the adjacent row.

32.7 Combination Serial Distribution

Incorporates two or more serial sections of SS in a single bed, with each section receiving a maximum of 500 GPD of effluent from a distribution box. See Combination Serial Distribution, sect. 9.0, on page 10.

32.8 Coupling

A plastic fitting that joins two SS pipe pieces in order to form rows. See sect. 3.3, page 3.

32.9 Daily Design Flow

The peak daily flow of wastewater to a system, expressed in gallons per day (GPD); systems are typically sized based on the daily design flow. Design flow calculations are set forth in the Massachusetts Rules. In general, actual daily use is expected to be one-half to two-thirds less than "daily design flow."

32.10 Differential Venting

A method of venting an SS System utilizing high and low vents (see sect. 27.2, page 18).

32.11 Distribution Box or "D-Box"

A device designed to divide and distribute effluent from the septic tank equally to each of the outlet pipes that carry effluent into the SS System. D-Boxes are also used for velocity reduction, see Velocity Reduction, sect. 26.1.4, page 17.

32.12 Distribution Box (D-Box) Layout

A design in which each SS row receives effluent from a distribution box outlet. Such a system is also called a "parallel system" or a "finger system." See D-Box (Parallel) Distribution, sect. 8.0, page 9.

32.13 Distribution Box Manifold

A PVC configuration which connects several distribution box outlets together in order to equalize effluent flow. Refer to drawing in sect. 5.8, on page 4.

32.14 Double Offset Adapter

A double offset adapter is a plastic fitting 12 in. in diameter with two 4 in. holes designed to accept a 4 in. inlet pipe, raised connection, vent or vent manifold, and/or bottom drain, depending upon the particular requirements of the design configuration (see sect. 3.2, page 3).

32.15 End-to-End Configuration

Consists of two or more beds constructed in a line (i.e., aligned along the width of the beds). See sect. 9.1, page 10.

32.16 Fill Extension

Utilized in constructing Elevated (mound) Systems to blend the raised portion of the system with side slope tapering to meet existing grade (see sect. 6.3, page 8).

32.17 Flow Equalizer

An adjustable plastic insert installed in the outlet pipes of a D-Box to equalize effluent distribution to each outlet.

32.18 GPD

An acronym for Gallons Per Day.

32.19 GPM

An acronym for Gallons Per Minute.

32.20 High and Low Vents

Pipes used in differential venting. Detailed information about venting requirements can be found in Venting Requirements, sect. 27.0, page 18.

32.21 LTAR

An acronym for Long Term Aceptance Rate.

32.22 MPI

An acronym for Minutes Per Inch and is the numerical value by which percolation rates (also called “perc. rates”) are expressed.

32.23 Multiple Bed Distribution

Incorporates two or more beds, each bed with Basic Serial, Combination Serial, or D-Box distribution and receiving effluent from a distribution box.

32.24 Non-Conventional Configurations

Have irregular shapes or row lengths shorter than 30 ft. in order to accommodate site constraints and are limited to 1-60 MPI. See Non-conventional Configurations, sect. 12.0, page 11.

32.25 Offset Adapter

A plastic fitting with a 4 in. hole installed at the 12 o'clock position which allows for connections from one row to another and for installation of venting (see sect. 3.2, page 3).

32.26 Percolation Rate

Also known as Perc. Rate, is a numerical indication of a soil's hydraulic capacity, expressed in minutes per inch (MPI.)

32.27 Pressure Distribution

A pressurized, small-diameter pipe system used to deliver effluent to an absorption field. Pressure Distribution is not permitted to be used with the SS System. The SS Systems are designed to promote even distribution without the need for pressure distribution.

32.28 Pump Systems

Utilize a pump to gain elevation in order to deliver effluent to a distribution box. See Pump System Requirements, sect. 26.0, page 17.

32.29 Raised Connection

A U-shaped, 4” diameter, PVC pipe configuration which is used to connect rows oriented in a serial configuration and to achieve the proper liquid level inside each row. See drawing in Components, sect. 3.4, page 3.

32.30 Raking and Tilling

Refers to methods of preparing the native soil that will be covered with System Sand or Sand Fill, creating a transitional layer between the sand bed and the soil. See Raking and Tilling Procedures, sect. 29.6, page 22.

32.31 Row

A number of SS pipe sections connected by couplings with an Offset Adapter on the inlet end and an offset Adapter or Double Offset Adapter on the opposite end. Rows are typically between 30 ft. & 100 ft. long.

32.32 Section / Serial Section

A group of interconnected rows receiving effluent from one distribution box outlet. Sections are limited to 500 GPD daily design flow maximum.

32.33 Serial Distribution

Two or more SS rows connected by a raised connection. Basic Serial distribution is described in detail in sect. 7.0 on page 9, Combination Serial distribution is described in detail in sect. 9.0, on page 10.

32.34 SHWT

An acronym for Seasonal High Water Table.

32.35 Side-to-Side Configuration

Consist of two or more beds arranged so that the rows are parallel to one another.

32.36 Slope (3:1)

In this Manual's illustrations, slope is expressed as a ratio of run to rise. Example: A slope with a grade of (3:1) is the difference in horizontal distance of (3) ft. (run) over an elevation difference of one (1) ft. (rise).

32.37 Slope (%)

Expressed as a **percent**, is the difference in elevation divided by the difference in horizontal distance between two points on the surface of a landform. Example: A site slope of one (1) percent is the difference in elevation of one (1) foot (rise) over a horizontal distance of one hundred (100) feet (run).

32.38 Smearing

The mechanical sealing of soil air spaces along an excavated, tilled or compressed surface. This is also referred to as "compacting." In all installations, it is critical to avoid smearing or compacting the soils under and around the field.

32.39 Surface Diversion

A natural or manmade barrier that changes the course of water flow around an onsite system's soil absorption field.

32.40 Surrounding Sand

Clean sand, free of organic materials and meeting the specifications set forth in 310 CMR 15.255. Surrounding Sand is used to raise the elevation of the system to meet required separation distance or in the over dig areas. System Sand may be used for Surrounding Sand.

32.41 System Sand Bed

System Sand area required/used in SS Systems. The System Sand bed extends a minimum of 6 in. below (1-60 MPI systems), 12 in. below (61-90 MPI systems), 6 in. above and 12 in. horizontally from the outside edges of the pipes in the system. System Sand must be clean, granular sand free of organic matter and must adhere to ASTM C-33 with no more than 3% passing the #200 sieve (see complete details in sect. 5.25, page 7).

32.42 System Sand Extension Area

Any portion of the System Sand bed that is more than 1 ft. away from SS pipe. The System Sand extension area is a minimum of 6 in. deep. A System Sand extension area is required on the down slope side of systems sloping more than 10% and extends a minimum of 3 ft. beyond the tall portion of the down slope edge of the System Sand bed (see ill. in sect. 6.3, page 8).

32.43 Topsoil (a.k.a. Loam or Soil Cover Material)

Topsoil, also known as Loam, is soil material cover capable of sustaining plant growth which forms the topmost layer of cover material above the system (see sect. 5.31, page 7).

33.0 Massachusetts Simple-Septic® System Installation Form

Installers must complete and fax or mail a copy of this form to the local approving authority and to:
Presby Environmental, Inc., 143 Airport Rd, Whitefield, NH 03598 Fax: (603) 837-9864
